Dr. G. K. T. Conn, at present reader in physics in the University of Sheffield, has been appointed professor of physics in the University of Exeter in succession to Prof. H. O. W. Richardson, who is taking up the chair of physics at Bedford College, London. Dr. Conn graduated in mathematics and natural philosophy from the University of Aberdeen in 1933, and then spent the following five years in the Cavendish Laboratory, Cambridge, working on research problems in infra-red spectroscopy, a field which has since engaged a major part of his activities. In 1938 he was appointed to an assistant lectureship at the University of Sheffield, and it is there that he has developed his research to an impressive extent. His contributions on the optical properties of metals have made him a recognized authority in this field and have led to a substantial number of papers on new techniques covering a wide range. Recently he has extended this work to semi-conductors, and the broad field of his activities may be described as the physics of the solid state. His publications include contributions on vacuum gauges and low-pressure measurements as well as the study of the magnetic properties of solids in connexion with investigations in other fields. Dr. Conn possesses an original and inventive mind, with an unusually wide range of knowledge and general interests. His freshness of outlook at all levels of teaching and his active participation in many student activities have combined to make him an invaluable member of the physics staff at Sheffield.

Paris Academy of Sciences : Elections

Prof. M. Fréchet, formerly professor of mathematics in the University of Paris, has been elected a member of the Geometry Section of the Paris Academy of Sciences in succession to the late Prof. E. Borel. The following have been elected *correspondants* for the Geometry Section: Prof. H. Milloux, professor of differential and integral calculus in the University of Bordeaux, in succession to the late Prof. H. Dulac; Prof. C. L. Siegel, formerly professor of mathematics in the University of Frankfurt am Main, in succession to the late Prof. H. Weyl; and Prof. Marston Morse, of the Institute for Advanced Study, Princeton, in succession to the late Prof. F. Riesz.

University of Leeds : Building Developments

A gift of £21,000 has been made by Brotherton and Co., Ltd., to the University of Leeds towards the building fund for the Chemical Engineering Section of the Department of Coal Gas and Fuel Industries. This firm has for many years given substantial financial help to the University for the purpose of furthering teaching and research in the Departments of Chemical Engineering, Chemistry, Textile Industries and Colour Chemistry and Dyeing, and, in particular, the late Dr. Charles Ratcliffe Brotherton bequeathed £50,700 for the development of chemical engineering, which has been invested pending the commencement of building work. The latest gift of £21,000 to the Department of Coal Gas and Fuel Industries brings the total received during the past twelve months for new buildings for this Department to £81,660; the cost will be £615,000, of which the Government, through the University Grants Committee, will find £450,000. The steel framework for the new buildings is now in place, and it is hoped to occupy them during 1958–59.

The present scheme of development of the University includes a number of new buildings and is the most ambitious ever undertaken by the University. That for the Man-made Fibres Section of the Department of Textile Industries is in its final stages of completion, and is due to be opened by the Duke of Edinburgh on June 29 next. Good progress is being made with an extension of the buildings now occupied by the Departments of Physics and Chemistry, which was started about twelve months ago, and it is anticipated that a new building for civil engineering and a new boiler house to serve the new buildings will be started on the Woodhouse Lane site in about twelve months; at the same time, the University will start the construction of a large new arts block at the Woodhouse Lane end of University Road, and it is planned to follow this after two years with new buildings for mechanical and electrical engineering. The cost of the whole scheme will be something in the region of £4 million, the greater part of which will no doubt come from the University Grants Committee. However, it will be necessary for the University to raise £500,000 towards the cost of these new buildings and their equipment, and up to date about £208,000 has been given or promised under deeds of covenant.

University Expenditure on Research

On May 31, in reply to questions in the House of Commons on the annual expenditure on fundamental scientific research by the University Grants Committee, Mr. H. Brooke, Financial Secretary to the Treasury, explained that grants are not normally earmarked for specific purposes and that research expenditure, therefore, is not separately distinguishable. He declined to comment as to the accuracy of the estimate that the amount is about £5 million and said that he is anxious not to embark on a policy of government earmarking of grants. The arrangements for the next quinquennium, he continued, will be the right moment to decide what future grants should be.

Mechanisms of Hearing and Balance

An up-to-date picture of some of the important topics of research on the ear and mechanisms of hearing and balance is given in a recent number of the *British Medical Bulletin* (12, No. 2 (May 1956): "Symposium on Neuro-Otology", pp. 70+4 plates; 15*s*.). Some new research techniques are described and illustrated in considerable detail. For example, by use of specially designed ultra-micro methods of analysis, it has been possible to estimate some of the electrolytes and organic fractions of the different labyrinthine fluids from small animals, even though the amount of fluid obtainable was sometimes as little as 0·1 µl. There are about a dozen separate articles in this number, and they include contributions on the comparative physiology of the otolith organs, fatigue and adaptation of hearing, and a fascinating chapter on the various types of inherited disorder of the labyrinth which are found in the different kinds of 'dancing' mice. This chapter ends with the sentence: "Further progress will largely depend on the degree of co-operation with specialists in related fields". It is just such publications as the present one which will increase that co-operation, by making clear to specialists in one field of research what is going on in related fields.

Rock Paintings and Engravings in Hyderabad

An interesting article has been prepared by Colonel D. H. Gordon and Dr. F. R. Allchin on some finds of rock paintings and engravings to the north of the Tungabhadra River in the Benakal Forest, Hyderabad (*Man*, July 1955). They were discovered by Leonard Munn, who photographed them and then copied them in colour on the photographs, and the dossier is now in the departmental library of the Indian Section, Victoria and Albert Museum, London. The drawings consist of human beings, horsemen, animals, signs, etc. Colonel Gordon, who has studied the rock-shelter art of the Central Provinces, India, for many years, has come to the conclusion that no part of this art dates back to a period earlier than the first half of the first millennium B.C., and that paintings and engravings continued to be made well into medieval times. The Benakal Forest art for the most part seems to belong to the dolmen period, as there are stone cists in the vicinity, with which they are probably to be associated. This would date some of the drawings to the first centuries B.C.; but a great deal of the art is clearly much later in date, as engravings have been found of Hindu sectarian symbols, scratchings and bruisings of umbrellas, as well as some drawings of temples.

Beef-Cattle Industry of Australia

The Commonwealth Scientific and Industrial Research Organization in Australia has published the results of a survey into the beef-cattle industry of the country (Bull. No. 278). The survey was carried out by W. A. Beattie, of the Division of Animal Health and Production of the Organization, and lasted from 1946 until 1952; it was designed to provide a background for the future planning of research. During the survey Beattie visited and examined all the beef-cattle producing areas of Australia and received co-operation from graziers' associations and primary producers. The survey aimed at determining and defining the structure of the industry as it has evolved in a variety of climatic environments on a large island continent, about one-third of which lies within the tropics. Attention was given to the conditions in each of the natural regions, action that may be taken to enable cattle to survive or thrive in them, the breeds of cattle available, methods of animal husbandry, disease and pest control, stock routes and transport, land tenure, labour, and the social structure of the industry.

Soil Science in India

In his presidential address to the Section of Agricultural Sciences of the forty-third Indian Science Congress, Dr. S. P. Raychaudhuri reviewed recent work in soil science in India with special reference to classification and survey. The first requirements of a basic improvement in Indian agriculture are a fuller understanding of the soils and a scientifically based programme for their better management. Indian scientists are tackling the innumerable problems presented by their soils on a broad front, and appear to be paying particular attention to the chemistry of soil fertility. Recent experience has shown remarkable responses to chemical fertilizers, and this offers immediate prospects of greatly increased yields. The majority of Indian soils are deficient in nitrogen, and the production as well as consumption of sulphate of ammonia are increasing steadily. Phosphate, by itself, is of more doubtful value, but increases response to nitrogen. Potash is generally adequate in Indian soils. Deficiencies of trace elements are reputed to be widespread, but little systematic study has been made of them. Much attention is being paid to salinity and alkalinity of irrigated soils, and soil surveys of irrigation areas have been of great value in preventing costly mistakes. Little work has so far been done on soil physics and microbiology, but the study of bacterial nitrogen fixation offers a promising field which is now being explored.

Besides irrigation surveys, fertility, land-use and soil-conservation surveys have been made in various parts of India, and this work is being extended. A basic system of classification for Indian soils is still lacking, and much field-work will have to be done before such a system can be devised. An All-Indian regional soil survey has been planned, and soil classes will be determined on a soil and geomorphological basis, with complementary chemical and physical determinations in the laboratory. Four regional centres are proposed in alluvial, black, red and laterite areas. The Indian Agricultural Research Institute now provides a two-year training course in soil survey.

Year Book of the Physical Society, 1955

The miscellaneous items which were previously published in the December issues of the Physical Society's *Proceedings* are now being published by the Society separately, entitled "Year Book of the Physical Society". The first such "Year Book", that for 1955, has been published (pp. 92; 10*s*.) and contains the following items: the texts of the 1955 presidential address, the 1954 Rutherford Memorial Lecture, the 39th Guthrie Lecture and the 18th Thomas Young Oration; abstracts of the lectures delivered by the recipients of the 31st Duddell Medal and the 10th Charles Vernon Boys Prize; obituary notices of five Fellows including Albert Einstein and G. F. C. Searle; and the report of the Council of the Society for 1954. In his Rutherford Lecture, Prof. P. M. S. Blackett describes his impressions of Rutherford and in particular refers to Rutherford's attitude to research and to the technical methods by which Rutherford achieved his astonishing output of important discoveries. He then discusses the problem of the proper relationship between the training of students in experimental technique and in theoretical knowledge, the difference between the present practice in British and American universities, and finally advances the practical solution of giving the experimental research worker an intense theoretical education in that part of theoretical physics which is narrowly centred on his experimental investigation. The Guthrie Lecture, entitled "Magnetism in Retrospect and Prospect", which was delivered by Prof. E. C. Stoner, consists of a survey of the advance in knowledge and understanding of the magnetic properties of matter during the past thirty years. Some of the outstanding experimental and theoretical problems are indicated, together with suggestions as to the kinds of experimental investigations required to elucidate the particular difficulties associated with metals. The basic data of colour-matching are the subject of the Thomas Young Oration, delivered by W. S. Stiles, of the National Physical Laboratory, Teddington, and a new determination of the colour-matching functions is described.

The Physics of Gas Flow at Very High Speeds

The Summer Meeting of the Physical Society will be held this year in the University of Manchester during July 16–17, and will be concerned with the flow of air and other gases at speeds so high that changes in kinetic energy are comparable with the energy required to produce interesting physical changes, such as dissociation, ionization and substantial emission of radiation. The implications for the aerodynamics of man-made projectiles travelling at extreme speeds, and also of meteors, will be included in the discussion. The shock tube will be discussed at length, both as regards design and instrumentation for use with very strong shock waves, and in connexion with the results so far discovered by its use. Prof. M. J. Lighthill, Department of Mathematics, University of Manchester, is organizing the sessions. Among those taking part in this meeting are: Mr. J. G. Davies (Jodrell Bank Experimental Station); Dr. Wayland Griffith (Palmer Physical Laboratory, Princeton University); Dr. D. W. Holder and staff (High-speed Section, Aerodynamics Division, National Physical Laboratory); Prof. M. J. Lighthill (Manchester): Prof. N. F. Mott (Cambridge); H. K. Zienkiewicz (Manchester). Non-members of the Society will be able to attend the meeting; inquiries should be addressed to the Physical Society, 1, Lowther Gardens, Prince Consort Road, London, S.W.7, marked for the attention of Miss Miles.

Commonwealth Fund Grants for Medical Education in the United States

The Commonwealth Fund, New York, has recently given grants of 4,850,000 dollars to seven university medical schools in the United States for use in whatever ways the schools consider most effective to improve their programmes of medical education. These grants, which are in addition to the sums expended for specific medical education projects during the fiscal year 1955–56, have been drawn from the Fund's capital assets and current income, and they bring to a total of 12,600,000 dollars the amount of such gifts made by the Fund since November 1955 to help the medical schools in the United States. The schools receiving the new grants are: Albany Medical College of Union University, 500,000 dollars; George Washington University School of Medicine, 500,000 dollars; University of Pennsylvania School of Medicine, 500,000 dollars; Boston University School of Medicine, 600,000 dollars; University of Rochester School of Medicine and Dentistry, 750,000 dollars; Johns Hopkins University School of Medicine, 1,000,000 dollars; and Stanford University School of Medicine, 1,000,000 dollars. During recent years the primary interests of the Commonwealth Fund have been in the field of health, particularly in medical education, medical research and community health services.

Institute of Biology: London Branch

The London Branch of the Institute of Biology held its annual conversazione on May 10 at the South-West Essex Technical College, Walthamstow, by courtesy of the principal of the College, Dr. H. Lowery. Guests were received by Dr. Lowery and Dr. H. O. J. Collier, president of the London Branch. Many biological topics were represented, from seals to bacteria: anatomy, ecology, ethology, microbiology, parasitology, pharmacognosy, physiology and biochemistry, and genetics were all represented. An interesting section was grouped together under "Improvisation and Gadgetry"; this was a valuable idea. The research worker is so often helped if he or one of his colleagues is versed in the art of gadget-making. It is often not simply a matter of 'making do', but of constructing something to do a job when no suitable apparatus already exists. Films and slides on four different topics were exhibited. It is customary for a guest society to be invited to make an exhibit; this year it was the Royal Institution, which displayed various historic documents and objects. The Branch also permits each year one firm of suppliers of apparatus to provide an exhibit. The layout of the exhibits was admirable, the Great Hall of the College giving ample space for complete inspection.

Symposium in Geneva on High-Energy Physics

THE European Organization for Nuclear Research is holding an international symposium on "High-Energy Physics" during June 11–23 in the Institute of Physics of the University of Geneva. Some three hundred scientific workers from twenty countries will attend the symposium; they will include approximately one hundred and sixty from the twelve member States of the Organization, about sixty each from the United States and the U.S.S.R., and a number from Australia, Canada, Czechoslovakia, India, Japan and Spain. In addition, about a hundred members of the scientific staff of the Organization will be participating. During the first week the main discussions at the symposium will be on novel features in the design and techniques of high-energy particle accelerators; the first few days of the second week will be devoted to newly developed techniques for the detection and measurement of fast particles, such as bubble chambers and over-compression cloud chambers, and during the latter part of the week π-mesons and the anti-proton will be considered.

Announcements

THE Geological Society of London has awarded the R. H. Worth Prize for 1955 to Mr. James Wright, and the Prize for 1956 to Dr. C. T. Trechmann; these Prizes are from a fund established under the will of the late Richard Hansford Worth, of Plymouth, "to provide a prize or prizes for the encouragement of amateur geological research". The Daniel Pidgeon Fund for 1956 of the Society has been awarded to Dr. K. A. Joysey, of the Department of Zoology, University of Cambridge, who is studying the variation in living and fossil echinoid species in order to assess the stratigraphic and systematic significance of this variation.

THE following, among others, have been appointed to chairs in the newly established Medical School of the University of Western Australia, Perth: *Anatomy,* Dr. D. C. Sinclair, University demonstrator in human anatomy, Oxford; *Medicine,* Dr. E. G. Saint, director of the Clinical Research Unit in the Royal Perth Hospital, Western Australia, and formerly of the Department of Industrial Health, King's College, Newcastle upon Tyne; *Microbiology,* Dr. N. F. Stanley, director of the Institute of Epidemiology and Preventive Medicine, Prince Henry Hospital, Adelaide.

THE College of Technology, Bristol, in collaboration with the Regional Council for Further Education for the South West, has arranged a course during July 6–7 on "The Applications of Radioactive Isotopes in Industry and their Uses as Tracers". The course is designed for chemists, engineers and technologists from industry. The fee, exclusive of accommodation, is one guinea. Further information can be obtained from the Department of Chemistry and Biology, College of Technology, Bristol 1.

A SUMMER course on "Oilfield Reservoir Engineering" will be held in the University of Birmingham during July 2–28. The course, which will be residential, will comprise lectures by members of the Petroleum Production Department of the University and specialist lecturers from industry, including, in particular, the British Petroleum Co., Ltd. Further information can be obtained from H. Gilmour, Petroleum Production Department, University, Edgbaston, Birmingham 15.

THE Association of Applied Biologists will hold its summer meeting in Northern Ireland during July 19–21. After the reading of a number of papers on July 20 at The Queen's University of Belfast, the succeeding days will be devoted to tours of the Counties of Antrim, Londonderry, Down and Armagh. Further information can be obtained from the honorary local secretary, Dr. J. Colhoun, Department of Mycology and Plant Pathology, The Queen's University, Belfast.

A TWO-DAY summer meeting of the Royal Meteorological Society will be held in the University College of Wales, Aberystwyth, during July 26–28. On the first day there will be papers on ionization methods of measuring air density and a discussion on airflow, and on the next day papers on aspects of local climatology will be followed by a discussion on orographic effects in relation to rainfall. Further information can be obtained from the Assistant Secretary of the Society at 49 Cromwell Road, London, S.W.7.

A CONFERENCE on "Magnetism and Magnetic Materials", organized by the American Institute of Electrical Engineers in co-operation with the American Physical Society, the American Institute of Mining and Metallurgical Engineers, and the Institute of Radio Engineers, will be held in Boston during October 16–18. Those who wish to read papers should send in the titles by June 15, and abstracts by August 1, to T. O. Paine, Measurements Laboratory, General Electric Company, West Lynn, Mass., from whom further information can be obtained.

A SYMPOSIUM on "X-Ray Microscopy and Microradiography", sponsored by the International Union of Pure and Applied Physics, will be held in the Cavendish Laboratory, Cambridge, during August 16–21. The symposium is intended to be a gathering of those with some direct experience or interest, rather than a large public conference, and primary emphasis will be placed on the physical methods, in theory and practice. Sessions are planned on the reflexion, contact and projection methods, respectively; sessions will also be devoted to applications in biology, medicine, metallurgy and other fields, including industrial applications. Further information can be obtained from Dr. W. C. Nixon, Cavendish Laboratory, Cambridge.

THE eleventh annual conference and exhibition of the Instrument Society of America will be held in New York during September 17–21. The exhibition, which will be in the Exhibition Hall of the New York Coliseum, is for manufacturers and their representatives to display their range of instruments and control apparatus used in scientific, technological and engineering work; in particular, emphasis will be placed this year on the application of instruments to automation in industry. Further information can be obtained from the exhibition manager, Fred J. Tabery, Eleventh Annual Instrument-Automation Conference and Exhibit, 250 West 57th Street, New York City.

THE PRESENTATION OF SCIENCE TO THE PUBLIC

"WHY do scientists want to communicate science to the public, while lawyers do not show any such desire to communicate law ?" To answer this question, asked by Dr. H. J. T. Ellingham in the recent symposium on "The Presentation of Science to the Public", is to explain why it was organized. Unlike lawyers or doctors, scientists work in comparative isolation from other people, and so they are apt to feel, as Dr. Ellingham put it, a little misunderstood. Scientists are aware that the general public sometimes fears or dislikes science, which makes some of them keener to explain how their work may ultimately be valuable to everybody. Knowing, too, that theirs is a social activity, which depends in the end on public support, some scientists believe that they owe society an account of their doings. If they themselves do not help to give this account, then others less informed may give a misleading version. Finally, the popularization of science helps to recruit young people to a scientific career and to incline their elders to accept scientific findings.

For many years, therefore, scientists have felt a need to inform the public about science, and a few of those who responded to this feeling in the past, such as Thomas Henry Huxley, achieved a skill that can scarcely be bettered. New discoveries and inventions, new ways of presenting information and a new public require the problem to be tackled over again in every generation.

For such reasons the Institute of Biology (London Branch), the Royal Institute of Chemistry (London Section) and the Institute of Physics (London and Home Counties Branch) jointly organized a symposium on the subject, which was held on March 21 in the Senate House of the University of London under the chairmanship of Mr. A. L. Bacharach. The symposium was opened with papers by three experts in different media of presentation: Dr. Archie Clow (sound radio), Mr. A. W. Haslett (printed word) and Mr. James McCloy (television).

Dr. Clow distinguished two main methods of communicating science by sound radio—the talk and the "dramatized feature". The talk, with which he has been mainly concerned, presents the scientist together with the science, and the requirements for its success are four: something to say, a valid reason for telling the public, imaginative treatment, and ability of the scientist to perform. Since radio is paradoxically an intimate medium, the art of putting good conversational English into the script is fundamental. A radio talk differs from a printed article not only in style, but also because the listener cannot go back to consider again what he has not understood. The order of presentation of a radio script has to be very carefully planned: it should arrest the listener's attention with the first sentence, it should never allow him to lose the thread, and repetition is no sin.

Dr. Clow said that the knowledge of the listener should not be over-estimated. Of a group of 21-year old soldiers, the bulk knew that microbes cause disease, less than half that living organisms cause fermentation of beer, and about one in twenty that they turn milk sour.

Mr. Haslett discussed both readers and authors. Of readers, he said that they need interest, knowledge and general education. The question of who should write for these rather rare characters depends on the technical level of treatment in a channel of communication which begins with a letter in *Nature* and ends with a man in a public house. On highly technical levels the scientist, who knows more about the subject but less about how to explain it, should be the author; but at the other end of the scale, the professional science writer is essential. In between, both should collaborate.

Advising on how to write science, Mr. Haslett leaned heavily on Fellows of the Royal Society, individually and collectively. He passed on their recommendations to use short words and simple sentences, not to write for the half-dozen people in the world specially interested, not to be afraid of making a fool of oneself and to remember that no one really likes an equation. He also stressed the value of giving an honest account of how a discovery has been made, if by chance or through error, rather than tidying it up to look logical.

Mr. McCloy said that a television programme looks like film but is the child of radio. It differs from film in being a live act, in which the commentator visibly takes part. Science is a 'natural' for television, since experiments, demonstrations, models, charts, films, discussions and comment can all be built into one programme. As science programmes reach an audience of several millions, they have to be easily understood. It follows that a good science television broadcast is difficult to give and easy to receive.

No main speaker dealt with the role of museums; but this gap was filled by Dr. F. A. B. Ward, who pointed out in the discussion that museums have the advantages of operating in three dimensions, and of being able to present historic notebooks, apparatus and machines.

Discussion centred mainly on what may be called the problem of 'resistance', which has two sides: resistance of the public to understanding science, and resistance of the scientist to telling the public about it. As might be expected, the scientists joining in the discussion were more aware of resistance on the part of the public, while the professional presenters of science were at least equally concerned at the resistance of the scientists themselves.

The discussion was opened by one member of each participating Institute. All the openers considered how science may be presented in a way that people can easily take in. Speaking from long experience, Dr. Maurice Burton advocated stressing the personal note and telling a story. Dr. Kenneth Pankhurst preferred the word 'communication' to 'presentation', because the former implies a certain intimacy between the giver and taker of information. Sincerity and enthusiasm are essential, but they must be accompanied by skill in the medium used. Mr. Geoffrey Parr deplored inadequate illustration in popular science books; Beatrix Potter achieved the ideal relationship of words to pictures in "Peter Rabbit", and, as in "Peter Rabbit", illustrations should be coloured.

Mr. T. A. Margerison, on behalf of the Association of British Science Writers, welcomed the symposium, which he thought was the first of its type. He said there can be no question of the *élite* scientist spreading scientific enlightenment to the lay public, because the problem of spreading science among scientists is just as urgent as that of spreading it among the public at large.

Mr. Maurice Goldsmith discussed the resistance of scientists to appearing on television. In producing a weekly television magazine, he has found that a proportion of scientists hesitate to co-operate. Some are needlessly afraid of being used for commercial ends, others feel it beneath their dignity to appear on television or perhaps fear the disparagement of their colleagues, while some do not feel that anything can be achieved in the space of four minutes. He believes that scientists do not realize that 'cathode ray tube time' is quite different from any other form of time they know. It provides the opportunity for a new experiment in the popularization of science, enabling the scientist to put forward what he wants to say to an audience of five million.

The communication of science to scientists and to the public may be regarded as extensions of one another. It follows, as Mr. A. L. Bacharach[1] pointed out in a preceding symposium on "The Communication of Biological Knowledge", that the same underlying principles apply to the communication of science, whatever the audience. No mind, however good, can take in unfamiliar things without effort. The scientist, familiar with his own special field, should therefore present it to others (technically qualified or not) in such a way that the effort required is not beyond their capacities. Bad presentation on any level should be suspected as a cloak for muddled thinking or poor research. The present symposium, which showed that a representative sample of scientists recognizes such truths, may become a small landmark.

H. O. J. COLLIER

LOW-TEMPERATURE CRYSTALLOGRAPHY

MEETING IN OXFORD

THE first joint conference of the X-Ray Analysis Group of the Institute of Physics and of the Low Temperature Group of the Physical Society was held at the Clarendon Laboratory, Oxford, during April 12–13 under the joint chairmanship of Dr. K. Mendelssohn and Mr. H. P. Rooksby. The subject of the conference was "Low-Temperature Crystallography", and the invited speakers dealt with both the technical aspects of X-ray work at temperatures down to 1° K. and also with the actual type of experiments where a low temperature is an advantage.

The first session was opened with an introductory paper by Sir Francis Simon (Clarendon Laboratory, Oxford). In this he emphasized that transitions which were not thought possible a few years ago do take place at low temperatures and that X-rays are one method of investigating the nature of these transitions. X-ray analysis can be used for giving information on the state of order of a system, this order being determined by the influence of the interaction forces between the components of a system. Order can exist only at low temperatures, and perfect order is only possible at the absolute zero. What we mean by a low temperature depends, of course, on the system we are considering; for diamond 1,000° K. is low, whereas for hydrogen 50° K. is high. X-rays can also give information on the form of the vibrational spectrum, and a combination of X-ray and thermal data should prove useful in entropy calculations based on the third law.

Dr. M. Blackman (Imperial College, London) dealt with the theoretical aspects of the effect of temperature on the reflexion of X-rays. He showed that from a generalized form of the Debye–Waller theory for a complex crystal, a characteristic temperature Θ_x can be calculated, and this can be compared with the characteristic temperature, Θ_{el}, derived from elasticity theory. The theoretical value of the ratio Θ_x/Θ_{el} for sodium chloride and potassium chloride did not agree with the ratio obtained from experimental results, and this discrepancy cannot, as yet, be resolved.

In a paper on a theoretical study of the variation of vibration amplitudes with temperature in some molecular crystals, Dr. D. W. J. Cruickshank (University of Leeds) discussed how the root-mean-square amplitudes of the translational and angular oscillations in benzene and anthracene have been determined by three-dimensional Fourier refinements with anisotropic parameters. From these amplitudes the various characteristic temperatures have been determined, and the temperature variation of the vibrational and rotational oscillations has been calculated. These show that, for studying fine details of electron density, it is much more advantageous to take measurements at 90° K. (or better still at $\sim$ 20° K.) than at room temperature, but that little extra is gained in this particular work by taking readings below 20° K.

Dame Kathleen Lonsdale (University College, London), in her paper on the determination of Debye factors by intensity measurements at low temperatures, showed that there are two independent ways of determining the Debye factors for crystal diffraction spectra: one is the original method of comparing the intensities at different temperatures with due regard to the existence of zero-point motion; the other uses the intensities at one temperature only, taking account of the positions and motions of the atoms as determined through a complete structure analysis. These methods have been compared from data on urea, and they have been shown to agree better than might have been expected, bearing in mind the possibility of change of atomic parameters with temperature.

Discussing low-temperature X-ray work on alkali metals and alloys, Prof. C. S. Barrett (University of Chicago) described an X-ray spectrometer in which metals can be cold-worked at temperatures down to 5° K. The X-ray studies show that, down to this temperature, lithium and sodium are the only alkali metals which partially transform on cooling. This transition is from the body-centred cubic to the hexagonal close-packed structure, the axial ratio in the hexagonal phase being very close to 1·633, the theoretical value for close packing. The transformation in lithium occurs at 70° K. On cold-working the lithium at low temperatures, there is a further transition, this time to the face-centred cubic structure. This does not appear to occur when sodium is cold-worked; but a similar transition does occur for solid solutions of magnesium in lithium.

Dr. W. B. Pearson (National Research Council, Ottawa) described X-ray cameras which have been built for use down to liquid-helium temperatures. These have been designed to have an accuracy of one part in 40,000, which is necessary for Debye–Scherrer photography if useful measurements of the change in lattice spacings with temperature are to be obtained. Other work to be done with these cameras includes the examination of structure changes in metals which are strained or subjected to high pressures at low temperatures.

The second session of the conference was opened with a paper by Prof. W. N. Lipscomb (University of Minnesota), who gave a general review of the techniques of low-temperature crystallography with particular reference to work on single crystals. After sketching briefly the history of single-crystal studies, he described the various methods of making single crystals for X-ray work. Many of these are gaseous or liquid at room temperature, and they require special methods for their production, the most common method being to crystallize the substance in a 'Pyrex' glass capillary. He also emphasized the need for keeping the production of frost down to a minimum, which can be done either by air-conditioning or by using a stream of dry air directed on to the apparatus. The consumption of liquid nitrogen, for cooling the specimen, can be quite considerable; for maintaining the specimen at −180° C. four litres per hour are required. Later speakers at the meeting, however, described cooling methods in which the consumption is much lower. Prof. Lipscomb's has been used for the completion of *hkl* data in B_5H_{11} and also for the investigation of transitions in ethylene chloride, hydrogen cyanide and nitrogen trioxide.

Dr. Aafje Vos (Laboratory of Inorganic and Physical Chemistry, Groningen) gave a review of recent Dutch X-ray work at low temperatures. This type of research has been done both at Amsterdam and at Groningen. In Amsterdam measurements on the electron-density projections of phthalic acid at −150° C. show an appreciable gain in resolution over those taken at room temperature. Low temperatures were also used in the investigation of the molecular compound of symmetric trinitrobenzene and benzene. At room temperature, pictures of the triclinic crystals showed a diffuse background with approximately hexagonal symmetry. This diffuse background disappeared completely at −150° C. The effect is probably due to independent thermal vibration of the individual molecules, and it seems most probable that the benzene molecules are responsible. In Groningen the crystal structure of 1,8-diphenyl-1,3,5,7-octatetraene has been examined at −100° C. in order to increase the accuracy of the determination of the bond-lengths. Standard deviations of about 0·003 A. and 0·04 A. were obtained for the co-ordinates of the carbon and hydrogen atoms, respectively. The use of low-temperature measurements has probably decreased the inaccuracy of the bond-lengths by a factor of two, and this is important if the experimental values are to be compared with theory. While in most of this work the specimens were cooled by a stream of cold air, another technique was described in which liquid nitrogen was dropped directly on to the specimen to cool it. In this apparatus the consumption of liquid nitrogen was 0·5 lit./hr.

Recent low-temperature crystallographic studies in France were described by Dr. A. J. Richard (Kodak-Pathé, Paris). This work was done at the Laboratoire Central des Services Chimiques de l'État. A Weissenberg camera was used in the temperature range − 160° to 20° C., the specimen being cooled by nitrogen gas obtained by boiling liquid nitrogen wit an electric heater. The temperature variation ove several hours was not more than five degrees, an during a period of one hour it was less than on degree. Structure studies were undertaken on nitri acid and its one- and three-molecule hydrate (V. Luzzati); one-, two-, three-, four-, five and seven-molecule hydrates of sodium hydroxid (P. W. Hemily); sulphuric acid and several compounds of the tertiary system nitrogen pentoxide–sulphur trioxide–water (R. Pascard); salicylic anhydride (Mme. P. Bourre); and acetaldehyd (A. J. Richard).

Another apparatus for maintaining specimens a low temperatures was described by Dr. J. H. Robertson (University of Leeds). In this the cold gas stream is again used for cooling, in order to give the minimum of interference with the X-rays, and by careful design the consumption of liquid nitrogen has been reduced to 1/7 lit./hr. The gas flow is very steady, the variation being only about 1 per cent over a period of 4½ hr. While the apparatus has not as yet been used with liquid hydrogen, it is hoped that it will be satisfactory in the temperature range down to 20° K.

Mr. M. H. Francombe (Research Laboratories, General Electric Co., Ltd., Wembley) gave a paper on the application of low-temperature powder photography to studies of magnetic and dielectric phenomena. A 19-cm. camera which incorporates a gas cooling system for the specimen was described and exhibited. The apparatus has been used for studying structural changes which occur in antiferromagnetic, ferrimagnetic and ferroelectric powders.

A paper by Dr. J. A. S. Smith (University of Leeds) showed how nuclear magnetic resonance measurements at low temperatures can give additional information in structural analysis. A general review of nuclear magnetic resonance methods was given, taking as an example work on benzene and ammonium chloride in which the behaviour below and above their nuclear magnetic resonance transitions was compared. From the variation of the line-width and relaxation-time in and above the transition region, the predominant molecular motions in the crystals could be investigated. In another series of experiments low temperatures were used to remove the narrowing effects of molecular motion on the line-width. This work has been done with sodium borohydride, hydrazinium oxalates and several hydrates. The results seem to cast further doubt on the existence of the ion H_4O^{++}.

Dr. C. H. Shaw (Ohio State University) read a paper on an X-ray determination of the structure of liquid helium. This work, which was done in collaboration with W. L. Gordon and J. G. Daunt, used proportional counter techniques for determining the intensity of the X-rays scattered by the liquid helium. Beryllium windows, 0·002 in. thick, were used to admit the X-rays through the vacuum jacket into the cryostat. The background count was reduced to 4 per minute. At scattering angles greater than 60°, no difference was found in the form of the diffraction patterns at 1·4 and 4·2° K. The low-angle results, however, which were taken at 1·4, 2·4 and 4·2° K., showed that there was a change in correlation number as the temperature was reduced, but that there seemed to be no definite change associated with the lambda point. X-ray measurements on tungsten showed that there was a maximum in the characteristic temperature, Θ, at 17° K. The existence of uch a maximum can also be derived from measurements of specific heat. In the discussion, Dr. M. lackman stated that on theoretical grounds this maximum is very difficult to explain.

In a paper on measurement of lattice parameters and thermal expansion at low temperatures, Prof. . O. Jones (Queen Mary College, London) described work done in collaboration with B. S. Figgins and . P. Riley. The apparatus was designed so that only the specimen was at the low temperature, and an accuracy of 1 in 10^5 in the measurement of the lattice parameter could be achieved. The temperature could be kept constant to 0·05 deg. at the lowest temperatures. So far, measurements of the lattice parameter (and hence of the thermal expansion) of aluminium have been carried out between 0° and 125° K. The results confirm earlier work of Bijl and Pullan, that at low temperatures there is a considerable deviation from Grüneisen's law. Measurements on solid argon are also in progress. In connexion with this work, Dr. E. R. Dobbs (Queen Mary College, London) gave a short contribution in which he described a simple back-reflexion camera for experiments on solidified gases down to 77° K. This has been used for work on solid krypton.

Mme. L. Couture (Centre National de la Recherche Scientifique, Bellevue) described work, done in collaboration with P. Jacquinot and I. Tsujikawa, on optical observations of transition in crystalline hydrates at low temperatures. The experiments showed that the absorption spectra of some substances (in particular, certain of the alums) changed at low temperatures, and these results were compared with corresponding changes which had been found in measurements of paramagnetic resonance. Complete agreement between paramagnetic and optical results was not achieved, but nevertheless the optical experiments confirmed that changes in crystalline structure do occur at low temperatures, especially in some of the chromium alums.

The conference showed that, while a large amount of X-ray work is already being done at temperatures down to 77° K., using liquid nitrogen as the coolant, not very many experiments have been done at lower temperatures, using liquid hydrogen or liquid helium as the coolant. There is still a very wide field of research open to anyone who has the necessary cryogenic facilities. In addition to the lectures already described, an evening discourse, entitled "Molecular Crystals", was given by Prof. J. D. Bernal (Birkbeck College, London).

In a meeting of the X-Ray Analysis Group which preceded the joint conference, a discussion was held on the collection and classification of crystallographic data for determinative and reference purposes. The discussion was opened with contributions by Dr. J. W. Hughes (University College, Cardiff) on the A.S.T.M. index, Prof. E. G. Cox (University of Leeds) on the single-crystal index, Dr. M. H. Hey (British Museum) on the Barker index of crystals, and Dr. L. E. Sutton (University of Oxford) on a bond-length index. Dr. W. B. Pearson (Ottawa) gave details of the index of metals and alloys which should soon be available. Several speakers in this discussion emphasized the need for research workers to send in their crystallographic and X-ray data to the compilers of the various indexes. Many of the data are obtained as an incidental part of some other research, and very often they are not published. Hence, they are overlooked when reference books are being written.

A full account of the conference will be given in the *British Journal of Applied Physics*. The next conference of the X-Ray Analysis Group will be held in London during November 16–17; two sessions will be devoted to biological structures, and one session to computational methods.

H. M. ROSENBERG

DIGITAL COMPUTER TECHNIQUES

A CONVENTION on "Digital Computer Techniques" was held in London at the Institution of Electrical Engineers during April 9–14, at which more than fourteen hundred persons attended, including 127 delegates from overseas countries. These figures emphasize the rapid growth of interest in this field, since at a similar convention, held three years ago, only two hundred in all were present. On the evening of April 9, after the convention had been opened by the president of the Institution, Sir George Nelson, an inaugural address was given by the president of the Royal Society, Sir Cyril Hinshelwood, and this was followed by an introductory lecture by Prof. F. C. Williams. During the next three days, fifty-eight papers were read. The papers had been divided into two groups: those of general interest, and those of interest to specialists. Normally, a general and a specialist session were held simultaneously, so that in this way both the non-expert and specialist were satisfactorily accommodated. On the last two days of the convention, visits to typical computer installations were made. These visits had been arranged with the co-operation of commercial companies, government establishments and universities; nearly nine hundred delegates availed themselves of these opportunities.

In his address, Sir Cyril Hinshelwood referred to the diverse lines of thought which have been successfully combined in the computing machine of to-day. Essential contributions have come from the theory of numbers, the relations between mathematics and logic, the discovery of various electric and magnetic phenomena, and the invention of the thermionic valve. He emphasized that the philosophy, in this case of machine design, preceded the actual construction and thus was not an afterthought about results, as it sometimes is. Having introduced the computing machine in this way, he then turned to view and speculate upon the interesting and exciting panorama which is beginning to unfold before us. On the scientific side there is now the prospect of solution of hitherto intractable problems; in the business world the mechanization of all kinds of clerical work and accountancy can be contemplated; and in industry the process of automatic control can be improved and carried a further step towards the final goal of complete 'automation'. The use of machines in this way must effect a displacement of man-power, and could amount to another industrial revolution. Sir Cyril Hinshelwood expressed the hope that any necessary redistribution of labour would be carried out without any serious results from the human and economic points of view. Finally, after a brief excursion into the seemingly age-old problems of 'Can machines think?' and the 'machine–brain analogy', he concluded by expressing his admiration of this work and his great confidence in its future.

In his lecture, Prof. Williams indicated the rapid development in the field of digital computers by considering the history of a typical computer installation, namely, that at the University of Manchester. Parallel developments have occurred elsewhere, but he selected this installation because of his familiarity with it. During the period 1946–56, two large-scale machines and one experimental transistor machine have been constructed. A commercial version of the first large-scale machine has been in continuous operation since 1951 and has now completed some 17,500 hours of useful computation. During this period, thirty-four different groups of users drawn from other universities, government establishments and industrial firms have operated the machine. Furthermore, 104 people have been trained to use the machine, and sixty-six scientific papers have been published using machine results. A commercial version of the second large-scale machine will be in operation at the University near the end of this year.

Prof. Williams went on to say that machines are attractive for many reasons: first, they can be universal so that they are capable of solving a large variety of problems; secondly, they are automatic, so that only a small amount of human intervention is needed; and finally, they are very fast, so that computation times are cut and, what is more important, many calculations previously impossible now become feasible. Machines are also relatively error-free; at the present time, on an average the machine makes one mistake in 4 million operations. What human being could compare! Moreover, though the hire of a machine appears expensive, in terms of cost per operation a machine is fifty times cheaper than a human computer would be. This latter comparison is only applicable if the machine is fully employed.

Looking a short distance into the future, Prof. Williams forecast machines which would be simpler to use, smaller in size, more economical in terms of power consumption, and also more reliable. However, the major steps, he stated, would be in the realization of the potentialities of these machines, and so a rapid expansion in the application of machines would result to the ultimate benefit of all. He concluded his lecture with the following remarks: "If at this juncture we are swollen headed with the sense of our achievements, or alternatively despair of further improvements, we have only to consider, for example, a rose seed. This very small particle contains all the data necessary for the manufacture of an unending and ever increasing supply of roses".

All the sessions on April 10 were of a mathematical nature and thus more of interest to the machine user. The topics of discussion in the specialist sessions were numerical analysis and logical design, five papers being presented. Computer applications were discussed in the general sessions, these being divided up into three sections: engineering and scientific calculation; business applications; and industrial control. Many papers were presented, the variety in the subject-matter illustrating immediately the universal nature of these machines. Topics ranged from testing the design of a proton synchrotron, to payroll calculations and the exploration of functional relationships in industrial processes. The main item of discussion during the day was a vital one, namely, that of machine reliability. Dr. I. J. Faulkner placed this particular problem in its right perspective, when he stated that progress towards a machine possessing a reliability of 100 per cent is very desirable, but no piece of equipment, whether electronic or not, yet possesses this feature. Further, until absolute perfection is guaranteed, systems dependent on a machine wi have to be designed to 'fail safe'. In the light of thes remarks, machines at the present time are adequatel reliable for a great deal of progress to be made Indeed, if the argument of waiting for more reliabl machines were adopted, nothing would be achieve for a very long time.

The general sessions on April 11 were devoted t machines existing or in the process of construction i Great Britain. Two large-scale computing machine are now commercially available. One is the 'Deuce' which possesses a high-speed store of approximatel 12,000 binary digits located in mercury delay-lines A magnetic drum-type store of capacity 260,00 digits is also provided which has electronic selectio of a block of sixteen heads. Further blocks of thes heads are selected by means of a novel mechanica system. Input and output facilities are provided b means of punched cards. In the second machine 'Mercury' magnetic core storage is used, and thi high-speed memory contains 40,000 binary digits Further storage of 650,000 binary digits is divide over four magnetic drums. Selection of the heads o these drums is entirely electronic. An interestin feature of this machine is its power to carry out 'floating point' arithmetic in a completely automati manner. Input and output facilities are at th present time by way of teletype tape. In addition t these two machines, numerous smaller-scale model are being constructed.

The two specialist sessions, one on rapid acces storage and the other on magnetic tape systems, als aroused great interest. At the first session Mr. N. H. Taylor, of the Massachusetts Institute of Technology, reviewed the history of the magnetic core store and gave an account of its present development in the United States. The climax was reached when he stated that a two-million digit store is well under construction at the Institute. In Britain the cost of the cores alone would be £80,000, which is greater than the complete cost of either of the machines already mentioned.

In the second session, two papers devoted to the development of tape systems moving the tape at speeds of the order of 100 in./sec. and with digit packing densities of approximately 100 digits/in. were presented. The tape is capable of moving in either direction and can accelerate up to full speed in the order of 15 m.sec. A further paper in this session discussed the design and operation of a head which is capable of reading digits off a tape even when this tape is stationary. At the present state of development, the head can identify digits with a packing density of 50 digits/in. The discussion revealed that many people realize the potentialities of this type of head.

At the first general session on the last day the design and construction of two point-contact transistor machines, one at Harwell and the other at the University of Manchester, were discussed. These operate at digit frequencies of about 100 kc./s. It is apparent that transistor development in Britain lags far behind that in the United States, since the latter already have transistor prototype machines functioning at a digit frequency of 5 Mc./s. At a subsequent specialist session, a lively debate took place on two papers utilizing techniques based on the combination of magnetic cores and junction transistors.

Other sessions on analogue/digital conversion and circuit techniques and components were held, but the main interest was aroused in a session discussing the computer in a non-arithmetic rôle. Here papers were presented on language translation, the playing of games and, finally, character recognition. A contribution was made by the U.S.S.R. delegates, who have been carrying out English to Russian translation on one of their machines since early in 1955. They assured their audience that the result was good Russian.

In conclusion, it can be stated that the convention brought together a large amount of detailed and expert technical knowledge in the various aspects of digital computers and their use. There is no doubt, too, that it proved valuable in some way to all who attended. The complete proceedings of the convention, containing the addresses, lectures, full text of all papers, and reports on the discussions, will be published in three issues as a supplement to Part *B* of the *Proceedings of the Institution of Electrical Engineers*.

DAVID B. G. EDWARDS

BRITISH AGRICULTURAL HISTORY SOCIETY

ANNUAL MEETING

SINCE it was founded in 1953, the British Agricultural History Society has held its annual meeting near Easter, and this year's meeting was at the Florence Nightingale Hall, University of Nottingham, on April 13. Officially, the annual general meeting is confined to one day—a business meeting in the morning followed by one or more papers read by members, and either more papers in the afternoon, or a visit to some point of interest. In addition, however, an after-dinner lecture was given in the evening of the previous day by Mr. John W. J. Higgs, curator of the Museum of Rural Life, Reading, and also honorary secretary of the Society. His lecture, which dealt with the problems involved in the identification and preservation of agricultural exhibits, was pleasantly informal and illustrated with lantern-slides. From the pictures it was clear that it is often difficult to discern the use of an object sent in, and even more so to date it. One such question arose out of the discovery on English farms of numbers of ox-shoes, or cues. It seems quite unlikely that bullocks on a farm would ever be shod, even if they were used for draught purposes, though they might be if used on roads. The explanation is probably that the animals were shoed before being brought from distant breeding-areas—Wales and Scotland, for example—and that it was not worth taking off any that remained on after the journey; eventually the shoes wore off and were dropped on the farm where the beasts were grazed. Many other similarly perplexing questions arise.

After the business meeting on April 13, the rest of the morning was occupied by two lectures, the first of which, given by Malcolm Gray, lecturer in economics in the University College of North Wales, Bangor, was on the "Consolidation of the Crofting System, 1750–1850". The story is extremely complex. Until 1815, population increased in the Western Highlands and Islands, and the number of crofts went up. Many were quite minute, only an acre or two. Attempts were made to meet the demand for land by rearranging the holdings, a kind of enclosure, but very different from the work done under Enclosure Acts in England. The kelp industry and the linen industry did a good deal to ease conditions, and the introduction of the potato was a boon. It provided more food from a given area than a grain crop. But it was attacked by disease, and the kelp industry lost ground in face of the competition of imported potash. These two factors, and a number of others, helped to make it difficult for the crofting system to survive. Dr. W. G. Hoskins, reader in economic history in the University of Oxford, gave the second lecture, which was on "Sheep Farming in Saxon England". There is only limited and scattered evidence on which to base such a lecture. A little is supplied by archæology, some by the study of place names, and some by a few documents. From these sources Dr. Hoskins has deduced the distribution of sheep in Anglo-Saxon England, and has estimated the total number as being about six million, or three or four sheep to each human being.

In the afternoon a visit was paid to the open fields at Laxton, now owned and preserved by the Government. Dr. J. D. Chambers, of the University of Nottingham, who is well known for his studies of the eighteenth century, acted as guide, and Mr. Rose, bailiff of the Manor, showed the fields.

THE PLACE OF UNIVERSITIES IN AUSTRALIA

THE Australian Vice-Chancellors' Committee has published in pamphlet form a symposium of papers on "The Place of the Australian University in the Community and Post-Graduate Studies in the Australian Universities", which were delivered during August 11–12, 1955, at a Commonwealth Inter-University Conference arranged in Australia by the Association of Universities of the British Commonwealth and the Australian Vice-Chancellors' Committee*. The first of these papers, by Prof. P. H. Partridge, on the Australian universities and Governments, gives a clear account of the closer dependence of Australian universities upon the State and Federal Governments, and this paper will assist those in Britain to understand some of the difficulties and dangers to which the Australian universities are exposed and also some episodes that may have puzzled those reading about them. Moreover, some of these dangers, such as that arising from the tendency in the thinking of Governments to subordinate research, advanced scholarship and post-graduate studies to the more elementary functions of making it possible for large numbers to gain degrees, could arise in Britain in appropriate circumstances; and Prof. Partridge notes other factors, such as the absence of any considerable proportion of university-educated men among Australian politicians, which have contributed to lack of understanding of the universities or respect for their autonomy in Australia. While he thinks the existing structure may be unhealthy and dangerous, he does not think that the independence of the Australian universities has been affected as much as might have been expected.

---

* Australian Vice-Chancellors' Committee. A Symposium on the Place of the Australian University in the Community and Post-Graduate Studies in the Australian Universities. Pp. 66. (Canberra: Australian Vice-Chancellors' Committee, c/o Australian National Committee. London: Association of Universities of the British Commonwealth, n.d.)

Prof. Partridge, moreover, offers some wise counsel to the universities which has relevance even in the more favourable circumstances of Britain. He suggests that, in spite of obvious dangers and difficulties, the universities should, in partnership with the Commonwealth and State Governments, attempt to evolve national policies of expansion and policies which will provide for some measure of specialization in the different universities, particularly in research. It is not unreasonable, he argues, to expect that the universities should at least explore the possibility of using as rationally as possible the greater resources placed at their disposal by the State, and there is much to be gained from the point of view of academic standards by not dispersing available workers too thinly over a comparatively large number of institutions. To take the initiative in such ways would, he believes, strengthen the universities themselves and might also facilitate the change in thinking of the State Governments which he also thinks desirable for the use of Commonwealth funds and to meet national needs. What Prof. Partridge urges has some relevance to the expansion of technological education in Britain.

The paper by Prof. D. M. Myers on the Australian universities and industry is essentially a factual account of these relations during the past hundred years, which emphasizes the factors dominating the present scene, such as the dependence of the Australian economy on its primary products, the extreme concentration of the population and of secondary industries in several major centres, and the unusual position in industrial research occupied by government institutions such as the Commonwealth Scientific and Industrial Research Organization. Prof. Myers comments on the unfavourable effect on the universities of this uneven distribution of the population, with the consequent tendency to parochialism and absence of interchange of staff, and he believes that it will be a happy day, too, for Australian industry when the universities regain a proper balance in their activities and are dependent on direct grants through an appropriate body set up for the purpose rather than on the support of a government body established for definite practical objectives. Prof. Myers makes some practical suggestions for future relations between Australian universities and industry on these lines.

Prof. A. Boyce Gibson's paper on the Australian universities and public opinion makes some sound points which should be noted in Britain, though he thinks that, in general, Australian universities have more to learn about public relations from the United States than from Britain. He suggests that the universities should do more to communicate their own scale of values and that the best way to open up public opinion is to do things the use of which is apparent to people uninterested in inquiry and scholarship: in science, by increasing welfare; in arts, by raising the standards of discussion and entertainment.

Prof. R. M. Crawford, discussing postgraduate studies in the non-science faculties, which he suggests are freer than the scientific and technical faculties from the restricting effects of the demand for highly trained professional artisans and research workers, does not believe that research and teaching staffs should be separated, but that more guidance could be offered at the undergraduate stage and that the quality of research rests fundamentally on the quality of the undergraduate schools. He stresses the importance of travel and of minimizing professorial administration. Dealing with postgraduate studies in science and engineering, Prof. L. H. Martin also deprecates the tendency in Australia to favour complete segregation of research from teaching and, in particular, to subjugate research and its proper function to the university's responsibility for postgraduate training. In the absence of a background of tradition, the Australian university, he urges, must foster close association with the community which supports it, and here the technological departments have a special responsibility. Prof. Martin is concerned that the average quality of science students has deteriorated in the post-war years. First-class talent is becoming rare among science graduates. There is evidence in Melbourne that the number of Ph.D. candidates in science is likely to decrease, and in 1954 there was only one applicant for the most prized travelling scholarship in science offered within member countries of the British Commonwealth. He also believes that lack of finance, including inadequate salaries, is the fundamental cause of frustration in Australian universities.

UNIVERSITY EDUCATION IN HUNGARY

At the eighth university conference organized by the International Association of University Professors and Lecturers and held in Vienna during September 9–14, 1954, Prof. L. Tamas, of the University of Budapest, described the development of university education in Hungary since 1945.

In recent years there has been a vigorous expansion in university education. In the year 1937–38 there were 12,000 students in the universities and the *grandes écoles* (13 per 10,000 population); in the year 1953–54 there were more than 53,000 such students (56 per 10,000 population). There were 473 foreign students in Hungary, and, with the exception of Australia, all quarters of the world were represented. In 1938–39 Hungary had 16 universities and *grandes écoles* with 37 faculties; to-day there are 33 universities and *grandes écoles* with 56 faculties. In 1952 and 1953 the State budget had given almost 260 million forints to the construction of new universities and the expansion of the older institutions.

Prof. Tamas also spoke of student conditions. In former years, the children of workmen and peasants, who formed the greater part of the country's population, represented 3½–4 per cent of the total number of students; to-day they constitute more than one-half of the total student body. Women students, to whom all careers are now open, represented 13 per cent of students in 1937–38. To-day the proportion is 26½ per cent. A noticeable change has taken place in the subjects read. Previously, more than one-half of university students and one-third of the total number of students followed courses in the faculty of law, while those who undertook technical and scientific studies formed much the smallest group. To-day this proportion is reversed: 47 per cent of the total number of students are registered in technical and science faculties, while 3 per cent only follow law courses.

A great deal of State assistance is given to university students. More than three-quarters pay no fees, the remainder pay minimum terminal charges. There are no charges for laboratory-work or examinations.

More than 90 per cent of the students benefit regularly from bursary grants, 17,000 reside in student hostels, and 24,000 feed in student canteens. There is medical and social aid.

Prof. Tamas discussed curriculum reforms which have been introduced and brought closer in line with the country's economic and practical needs, and the extent of the advanced and research work undertaken in the Hungarian universities.

RED FOX IN THE UNITED STATES

AN evaluation of the red fox in the United States has been made by Thomas G. Scott, on behalf of the Illinois Natural History Survey*, which suggests that the fox has shown no sign of declining in numbers and that it has unusual capabilities for survival despite keen competition; the opening-up of forest lands and the reduction or elimination of wolves and coyotes seem to favour foxes. Some reports on rabies outbreaks in the eastern United States indicate that the fox is fully capable of reaching population-levels which are too high to serve its own interests.

The role of the red fox as a predator appears to be the most important of the various factors affecting the economic position of this animal. It tends to take the foods which are most readily available, and thus its diet varies immensely both with the season and the environment. The diet does not reflect precise, automatic adjustments to changes in population-levels of specific prey. For example, during the spring and summer, when prey such as rabbits, mice and birds are found in increasing numbers, the frequency of occurrence of these items in the fox's diet declines where acceptable fleshy fruits and insects are available. Thus it would be unwise to claim or expect an increase in numbers of prey species in response solely to the reduction or elimination of red foxes. A large-scale experiment with the reduction of a fox population as a means of increasing a pheasant population in New York State resulted in the conclusion that "despite reducing the fox population to a very low level, fox control on the Seneca County area did not increase pheasant abundance appreciably and certainly not to a degree commensurate with the cost". Though foxes unquestionably prey upon vulnerably situated poultry, and to a lesser extent on small pigs and lambs, it seems that poultry losses result largely from failure of owners to follow recommended poultry-husbandry practices.

Foxes are among the most important vectors of rabies in the United States, and herein probably lies their greatest nuisance. People living in an area where rabies has been reported experience great mental distress, and may even have to suffer the physical discomfort of Pasteur treatment if attacked. It is certain that losses occur among livestock infected through the bites of rabid foxes. When rabies breaks out in a locality of high fox population, the disease is likely to continue until the foxes in that general area are virtually exterminated; this may take from one to three years.

The most desirable method known for bringing rabies outbreaks among foxes under control has proved to be population reduction by means of organized trapping; but whether the several million dollars that has been paid out during the past twenty years on fox bounties has been money well spent is a question open to doubt. Experience in Pennsylvania indicates "that probably 50 per cent or more of the mammalian predators (red fox, gray fox, and weasel) would have been killed regardless of the bounty". The bounty system cannot be directed efficiently toward the reduction of specific, excessive fox populations because the administrative areas in which funds are approved for bounties seldom conform with the particular areas needing attention. The economic demand for red fox pelts is at present very low. The sport of fox-hunting contributes to the reduction of fox populations, and the survey, which is well illustrated, discusses the ethical and æsthetic values involved in this sport.

STIMULATION OF YIELD FROM RUBBER TREES

A GOOD deal of work has been done at the Rubber Research Institute of Malaya, both before the Second World War and, more recently, on the stimulation of yield in the rubber tree *Hevea brasiliensis* by applications of vegetable oils (for example, palm oil) and various synthetic substances, and several aspects of this are described by E. D. C. Baptist and P. de Jonge in the *Journal* of the Institute (14, 355; 1955). A brief historical review is given of methods used for stimulating the latex yield of rubber trees, and experiments are described in which vegetable oils applied to lightly scraped bark below the tapping-cut resulted in large increases in yield.

The results of these early experiments provided a clear picture of the reaction of the tree to yield stimulation and led to the development and commercial use of yield stimulants. Similar application of a number of synthetic growth substances in an oil vehicle has also resulted in increases in yield and in the thickness of renewed bark above the cut. Repeated applications of the treatments at six-monthly intervals over a period of three years have not resulted in an increased incidence of 'dry' trees; but the yield response is found to decrease with each successive treatment. Monthly treatment with yield stimulants of renewing bark just above the tapping-cut has also resulted in greatly increased yields and in an increase in bark thickness; the latter is confined to the non-latex-bearing tissues of the outer bark. A study has been made of the effects of 2,4-dichlorophenoxyacetic acid (2,4-D) and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) on the rubber extraction area of the bark on tapping, the incidence of brown bast, rate and duration of latex flow, anatomical structure of the bark, and the properties of latex and dry rubber.

The response of the rubber tree to yield stimulants is shown to be influenced by the condition of the bark, the type of planting material, the tapping system, the composition and method of application of the mixture. An extension of the area of rubber extraction in the bark of trees in normal tapping as a result of treatment with yield stimulant has been demonstrated experimentally and is thought to account for the increased yields obtained and for the low incidence of brown bast after repeated treatment. The increase in bark thickness observed is caused by induced meristematic activity in the cortical and phloem regions, resulting in prolific development of undifferentiated parenchyma tissue, and not by activation of the vascular cambium. The rate and duration of latex flow are increased afte treatment with a yield stimulant, and there is slight decrease in the dry rubber content of the late which usually reaches its lowest value in the secon month following treatment.

PROPHYLACTIC ACTIVITY OF SURAMIN COMPLEXES IN ANIMAL TRYPANOSOMIASIS

By DR. J. WILLIAMSON and DR. R. S. DESOWITZ

West African Institute for Trypanosomiasis Research, Vom, Northern Nigeria

THE first, and still the most effective, prophylactic drug for bovine trypanosomiasis is 'Antrycide Pro-Salt' (a mixture of antrycide dimethylsulphate and antrycide chloride)[1,2]. Experience has shown that the maximum reliable prophylaxis obtainable with this drug is approximately two months[1-3]. The administrative work, however, required to locate and inject nomadic cattle six times a year at two-monthly intervals is usually too great to be practicable.

Some preliminary results of an investigation designed to extend the existing period of prophylaxis, using trypanocidal drugs in common use, are described here.

The possibilities of using a suramin–pentamidine salt complex to extend the pentamidine prophylaxis of human trypanosomiasis were indicated by Guimaraes and Lourie[4]. On the basis of an observation made by Lourie during a sleeping sickness campaign in 1939–41[5], these authors showed that suramin could inhibit many of the pharmacological or toxic effects of pentamidine, primarily by the formation of an inactive salt complex. Experimental confirmation of extended pentamidine prophylaxis in rats by this method has been reported by Schneider (see ref. 8), and by Cosar, Ducrot, Gailliot and Baget[6]; Beaudiment and Zozol[7] and Beaudiment, Cauvin and Leproux[8] have further shown that suramin can reduce the toxicity of pentamidine in man.

It seemed probable that suramin might form similar salt complexes with drugs active in bovine trypanosomiasis, which are all strongly basic compounds like pentamidine. Suramin was, in fact, found to form insoluble precipitates *in vitro* with solutions of ethidium and dimidium bromides, the *bis*-cinnolinium compound '528'[9], antrycide dimethylsulphate, and a new German diamidine-type trypanocide 'Berenil' (di-(amidinophenyl)-triazene (-N-1: 3) diaceturate)[10].

As ethidium bromide is the most active member of this group, prophylactic experiments in rats and mice were begun, using combined treatment with suramin and ethidium bromide. At this time, Dr. W. E. Ormerod kindly made available to us the results of his experiments on the suramin detoxication of antrycide dimethylsulphate[11], following an analogy between the pharmacological effects of antrycide and curare; the toxicity of the latter was known to be reduced by prior administration of acid dyes such as congo red[12], which is related to suramin.

Although initial experiments showed that some degree of prophylactic activity was being conferred on ethidium bromide by suramin administration, the toxicity of the former drug was not markedly reduced by simultaneous or prior treatment with a separat injection of suramin under widely varied conditions The quantitative basis of complex formation wa therefore examined, since, theoretically, one molecul of suramin, with six sulphonic acid groups, coul combine maximally with six molecules of ethidium or dimidium bromide, or with three molecules o antrycide, '528', 'Berenil' or pentamidine. Gravimetric analysis showed that the combining proportions did in fact approximate closely to th theoretical, and suspensions of the precipitated complexes prepared by mixing aqueous neutral solution of the drugs according to these proportions wer afterwards given throughout as a single injection.

Results in rats given a single subcutaneous maximum tolerated dose of the suramin complex o ethidium, dimidium, antrycide, '528', and 'Berenil' showed that there was a maximum decrease in th toxicity of these drugs of approximately 10-, 5-, 14 8- and 3-fold, respectively. Prophylactic experiment in rats and mice repeatedly infected intraperitoneally with a virulent strain of *Trypanosoma congolense* showed that suramin-complex formation induced o increased prophylactic activity in all the drugs tested but to a varying degree. In the case of dimidium ethidium, and '528' the increase was only of th order of a week or two; with 'Berenil' the increase was approximately five to seven weeks, and with antrycide dimethylsulphate, more than fifteen weeks

Suramin complexes of three trypanocidal compounds have been tested in cattle for prophylactic activity; these were antrycide dimethylsulphate–suramin, ethidium bromide–suramin and 'Berenil'–suramin. Since the 'Berenil'–suramin complex showed little prophylactic activity even at a dosage o 40 mgm./kgm., it will not be discussed in this communication. (Dosages throughout refer to the amoun of the basic drug present in the complex, and *not* t the total amount of the complex.)

The trials were carried out at the Institute's laboratories at Vom, which is in a tsetse-free area The animals used were zebu cattle and each wa given a *single* injection of drug-complex or, in th case of controls, the drug alone. The animals wer then challenged repeatedly with cyclically transmitted trypanosomes. This challenge was delivered by *Glossina palpalis* reared in the laboratory, which had first been given multiple feeds on an ox or sheep heavily infected with *Trypanosoma vivax*; subsequen sample dissections showed that 90 per cent or mor of the flies in each batch were infected. Batches o 100–150 infected flies were fed on each experimental animal for three consecutive days, and this challeng was repeated every ten to fourteen days until break able 1. PROPHYLACTIC ACTIVITY OF SURAMIN COMPLEXES IN ZEBU CATTLE

Drug	Dose*	No. zebu used	Prophylaxis afforded (days)
Antrycide dimethylsulphate (control)	5 mgm./kgm.	3	39, 41, 52
Antrycide pro-salt (control)	5 mgm./kgm.	5	69, 72, 75, 80, 91
Antrycide dimethylsulphate – suramin complex	10 mgm /kgm.	5	95, 95, 115, 120, 129
	20 mgm /kgm.	5	135, 146, 149; 2 animals still not infected at 196 days
	40 mgm /kgm.	5	162, 163, 179; 2 animals still not infected at 196 days
Ethidium bromide (control)	5 mgm /kgm	4	57, 102, 122, 147
Ethidium bromide – suramin complex	5 mgm /kgm	2	216; one animal still not infected at 217 days
	10 mgm /kgm.	3	None infected to date (217 days)

* Dosage of complexes refer to amounts of antrycide dimethyl-lphate or ethidium present in complex form.

rough occurred. Four strains of *T. vivax* were sed in this manner. The zebus were also challenged ith wild *G. longipalpis* from Southern Nigeria which ere infected with both *T. vivax* and *T. congolense*.

The results of these trials are summarized in able 1. No toxic symptoms were noted at any osages of complexes given. There was the usual welling due to the depot of drug, but the surrounding rea did not become inflamed or oedematous. It will e seen that considerably more drug in complex form an be given safely than the known maximum safe oses of the drug alone. This is especially true for ntrycide dimethylsulphate, where the maximum olerated dose of the drug alone is 5 mgm./kgm., but n complex form the maximum tolerated dose is 0 mgm./kgm. Detoxication is less marked in the ase of the ethidium–suramin complex, where 10 mgm./kgm. appears to be the maximum tolerated dose. This is compensated for, however, by the marked prolongation of prophylactic activity of ethidium complex at low dosage. Reference to Table 1 shows that in the case of the antrycide dimethylsulphate complex the ability to give more drug safely results in a markedly increased prophylactic period; at the highest dose used (40 mgm./kgm.), at least five and a half months protection can be relied upon.

Although the number of animals used for the ethidium-complex trial is small, there is every indication that this complex is the most promising. This is of interest since the prophylactic trials in small animals gave little indication of its activity in cattle. Seven months protection has been afforded by as little as 5 mgm./kgm. of complex, and at 10 mgm./kgm. no break-through has yet taken place after 217 days. A larger trial with the ethidium-complex is planned. A full account of these trials will be published elsewhere.

We are indebted to Dr. T. A. M. Nash, director of this Institute, for his continued interest and encouragement of this work. [March 28

DIAMOND AS A PINPOINT RADIATION COUNTER*

By W. F. COTTY

Diamond Producers' Association, 11 Old Jewry, London, E.C.2

SINCE van Heerden (1945) reported that silver chloride, at low temperature, would detect -particles, several other crystals have been found hich possess this property. In this work I am oncerned with only one of them, namely, diamond, room-temperature counter discovered by Woolridge, Ahearn and Burton[1]. A crystal with this dvantage makes the design of a practical crystal ounter much simpler, and my work has been hiefly concerned with investigating the possibilities the diamond may have of eventually being developed nto a useful pinpoint counter.

Besides its ability to count efficiently, the diamond as physical and chemical properties which make it n attractive material for use in a practical counter. f the counter were intended primarily for medical se, these properties would have added significance, specially the density of the crystal. Physically, its density is such that diamond has a stopping power early three thousand times greater than that of air, nd electronically, the density (and the γ-ray absorption) of carbon is of the same order as that of human tissue. Thus a high-speed particle would penetrate both diamond and tissue to about the same degree. Consequently, if the diamond counter were to be used to measure the dose-rate on patients receiving deep therapy or similar treatment, one would expect to get more accurate measurements than could be obtained with more conventional instruments. Furthermore, because of its chemical composition, diamond can be autoclaved and sterilized satisfactorily for use internally.

The advantages of the diamond as a counting crystal have been recorded elsewhere[2]. In contrast to its many desirable features looms the bugbear of polarization, due to the space charge which builds up inside a counting crystal and opposes the externally applied field, thus causing considerable reduction in the counting efficiency of the crystal. It is caused by the current carriers being captured by the trapping sites in the crystal. Since every diamond reacts differently, it was just possible that diamonds did exist which were electronically perfect enough not to be seriously affected by polarization. I therefore sorted through approximately a hundred thousand diamonds to test this possibility, and I am convinced that such diamonds occur in Nature. These diamonds make really efficient counters and will maintain a reasonably steady counting-rate for periods of several hours, perhaps indefinitely. For this test I used a 1-mc. γ-source (cobalt-60) placed at a distance of 1 cm. from the diamond. Such diamonds have been used for the past five years, and I classify them as structure-sensitive diamonds peculiar to certain diamond fields. Using small octahedra of 1 mm. side, Champion (unpublished work) has shown that the non-polarizing regions of a counting diamond fall into class 2 of his identification table for diamonds. My specimens, on the other hand, have varied widely in size and shape, and for sorting purposes I have had to rely on the ultra-violet fluorescence method for selecting counters.

---

* Substance of a thesis which was awarded the Insignia Award of he City and Guilds of London Institute in 1955

Ahearn has shown that under the influence of rays from a radioactive source a counting diamond, working in an electric field, will generate small pulses of current. Under these conditions, an electron and a positive hole will be created every time a high-speed particle communicates sufficient energy to a carbon atom. This is analogous to ionization in a gas. In a diamond, relatively free of electron traps, the electrons and the positive holes move in opposite directions with substantially the same velocity and, by placing the diamond in a suitably designed electronic circuit, the movement of the current carriers can be measured.

In the early laboratory experiments the diamond was placed as close to the grid of the pre-amplifying valve as possible, since the signal voltage is inversely proportional to the capacity of the circuit. For practical purposes, however, it is necessary to move the diamond some distance away from the pre-amplifier. This entails two alterations to the conventional circuit: (i) slight modifications to the electronic circuits, and (ii) a properly designed diamond holder. After some preliminary experiments, I found that the diamond may be conveniently mounted at the end of a thin, hollow metal tube or a flexible coaxial cable to form a probe. The length of the probe is limited by the amount capacity permitted in the circuit, but probes up to foot in length have been made and function sati factorily. In one instance the external diameter the probe was less than 3 mm. and, in this case, th volume of the diamond was probably no more tha two or three cubic millimetres. For best results th diamond should be cut to fit snugly into the end the tube. My method of mounting the diamond such a tiny holder is to have a hole drilled in th diamond just large enough to accommodate a ve thin wire. This wire acts as an anode and runs dow the middle of the tube. It is insulated from th outer metal holder, which is at earth potential. Th potential difference between the inner electro and the holder creates the energizing field for th diamond.

The pulses generated by the diamond under bombardment are of the order of microvolts and have be amplified considerably before they will opera conventional recording devices. A linear amplifier employed for this purpose. One of the limitations this type of amplifier is the noise which is generate by the pre-amplifying valve and its associated circuit This noise sets a threshold limit to the sensitivity the diamond counter at approximately 25 μV. Th in turn determines the lowest energy which can recorded by a diamond counter under present conditions; but for α- and β-sources usually used in th laboratory the diamond counter is as efficient counter as the Geiger counter[3].

To date, work on the diamond counter has bee confined to a limited number of research worke whose preliminary investigations have demonstrate some of its advantages and disadvantages. Th indications are, however, that it has possibilities ultimately being developed into a useful pinpoin counter suitable for specialized—probably medical—applications. The potentialities of the diamond i this field therefore merit fuller investigation.

ANTARCTIC ATMOSPHERIC CIRCULATION

By H. H. LAMB
Meteorological Office (Air Ministry), Harrow, Middlesex

IN 1951[1] I put forward the view that general attempts to interpret Antarctic atmospheric circulation in terms of a permanent low-level anticyclone surmounted by a permanent upper cyclone could not be reconciled with the sequences of daily synoptic weather maps of the southern hemisphere, which were then becoming available for the first time. In particular, the concept of permanency was untenable, as in the case of atmospheric circulation systems in other parts of the world.

The problems raised by (1) continuing nourishment (at least, in some degree) of the Antarctic ice-cap and (2) occasional observations of cyclonic winds and weather on the coast and by expedition parties in the interior of Antarctica could only be resolved in terms of a succession of changing weather situations. Evidence now exists that these situations embrace *inter alia* both (warm) anticyclones and (cold) depressions in which the respective circulation systems reach to great heights without change character[2,3].

It will be generally accepted that katabatic down slope surface winds are predominant at most point of the fringe of the ice-cap and, to a less exten probably on the higher parts of the inland ice. has also become clear that most of the active depres sions which skirt, or encroach upon, Antarctica hav closed cyclonic circulations extending at least up t the higher parts of the ice-cap, which are liable t be swept by gales and experience the frontal cloud and weather.

In collaboration with Instr. Commdr. G. Britton, R.N., I have lately confirmed and amplifie these conclusions by making statistical studies (*a*) the distribution of centres of depressions an anticyclones in high southern latitudes on the dail weather charts[4] analysed during 1947–49 by Britto and Morgan at the Royal Naval Investigations

Weather Centre at Simonstown, South Africa, and b) the percentage frequency of occurrence of urface westerly winds in all sectors of the coast of Antarctica and near the ice-edge at sea south of 0° S. Some of these results have already been published[5].

The geographical distribution of anticyclone centres ver the southern polar regions, derived from the Simonstown daily synoptic analyses of the southern emisphere, on 134 days when such deduction was possible during January–April and November 1947 nd March–April 1948, showed the main concentration of anticyclones displaced from the georaphical pole in the direction of the broadest part f Antarctica, perhaps as far north as lat. 85° S. in long. 40–50° E. This position is very close to the true centre of the ice-covered polar region, but may reflect an unconscious bias on the part of those analysing the daily charts to indicate the anticyclone as near to the South Pole as could be made to fit the vidence. It is also in reasonable agreement with the main cluster of centres of highest monthly mean pressure about lat. 82° S., long. 60° E. in the three years 1951–53 given by the Southern Hemisphere Daily Weather Analysis Project of the South African Weather Bureau, Pretoria[6]. There is perhaps some ground for preferring to believe the more eccentric position.

Careful assessment of all these data and re-examination of the weather logs of the main expedition ourneys of the past into the interior of Antarctica have made possible a reasonable estimate of the frequency of generally cyclonic weather situations over Antarctica (largely resulting from the encroachment of large travelling depressions from other atitudes) and has yielded unmistakable evidence of ndividual deep depressions as they passed inland over the ice.

The frequency of cyclonic situations in the interior, with westerly winds at the coast, may be given as about 5–15 per cent for different parts of the continent, though there are great variations from year to year. In some particular months (for example, March 1947) the percentage may have been 50 per cent or even higher. East Antarctica between lat. 0° and 90° E. is probably most nearly immune. Surprisingly, cyclonic situations and low pressures are more frequent in winter than in summer (with a possible reservation in the case of the Graham Land–Weddell Sea sector, where pressures tend to be relatively high both in December–January (summer) and in May–July (early winter)).

The majority situations (85–95 per cent) are quite various, though there is usually either a shallow surface anticyclone or a region of relatively high surface pressure and slack circulation somewhere over Antarctica, especially "East Antarctica" (where the continent is broadest), between the surrounding depressions. The central anticyclonic region, even when it is most clearly defined, sometimes takes up a position far out from the Pole in one sector or another for fairly long periods, and may at times be centred over the ice of either the Weddell or Ross Seas: disturbed conditions then usually prevail in the opposite sector.

Several cases are on record in which very deep depressions (mean sea-level pressures 927–945 mb. at the nearest coastal bases) passed inland south of the Adélie Land coast (lat. 67° S., long. 140–145° E.) and Ross Barrier (lat. 78° S., long. 160–180° W.), in all cases between late June and early October. At least two of these depressions passed south of Admiral Byrd's 1934 advanced base (Bolling Station) in lat. 80° S. on the Ross Barrier.

The occasional southerly gales experienced even in summer by all parties on the polar plateau between the Ross Sea and the South Pole would be consistent with depressions passing on a track near lat. 80° S. from the Ross to the Weddell or Bellingshausen Seas—the shortest track across West Antarctica. These gales blew up the general gradient of the ice plateau (that is, against the katabatic effect) between 88° S. and the Pole.

Independent summaries dealing with antarctic meteorology[3,7] suggest that there is now a good consensus of opinion among workers in various countries in support of my main thesis regarding impermanence of the antarctic anticyclones and great variability of the general weather situation, especially in winter.

The geographical distribution of the antarctic anticyclones, which is now becoming clear, has a corollary of some possible practical importance: the frequency of the gales which sweep the polar plateau should fall off from the Pole in the sector of East Antarctica, so that the "fairest weather route to the pole" (the phrase is Britton's) may be expected to lie across that part of the continent between about the 0° and 90° E. meridians. This appears to be the preferred region for anticyclones and is relatively infrequently encroached upon by depressions. Moreover, in longitudes between 20° W. and 20° E., east of the Weddell Sea, the general circulation around these anticyclones (which are the heavily predominant situation in summer, that is, December–January), should tend to oppose and offset the general katabatic drainage of cold air off the ice-cap, which blows in the face of expedition parties on the ground making for the polar plateau. This suggests that, on the whole, there should be relatively least trouble with headwinds, blizzards and snow in longitudes between about 20° W. and 45° E., whatever the geographical difficulties of the route might be. At the same time, expeditions must always reckon with the characteristic type of variability (most pronounced between March and October) of the Antarctic atmospheric circulation, which is liable to long spells, lasting in extreme cases up to two to three months, of unusual circulation patterns when any part of the interior may be liable to experience cyclonic weather.

The same work on the meteorology of the far south led to certain hypotheses about major geographical features—a great trough and a great ridge—in the broadest, unexplored region of the Antarctic continent in eastern longitudes. One of these hypotheses has recently been confirmed by observation (*The Times*, March 7, 1953).

I am indebted to the Director of the Meteorological Office for permission to publish this account.

Isolation of Two Myoglobins from Horse-heart Extracts and the Determination of the Molecular Weight of the Main Component

The method developed by Boardman and Partridge[1] for the separation of hæmoglobins on columns of the ion-exchange resin, 'Amberlite *IRC*-50' (*XE*-64), has been applied to the purification of horse carbon monoxide myoglobin, with the result that two carbon monoxide myoglobins were isolated from extracts of horse heart. The component carbon monoxide myoglobin (*B*) was present to the extent of about 10 per cent of the main myoglobin fraction, carbon monoxide myoglobin (*A*). Each fraction was shown to be homogeneous in the ultracentrifuge, and when examined in a Hilger 'Uvispek' spectrophotometer each gave an absorption spectrum typical of carbon monoxide myoglobin. The molecular weight of the main component was determined from measurements of osmotic pressure[2] and a detailed amino-acid analysis was carried out by the procedure of Moore and Stein[3].

A water extract from a perfused horse heart was saturated with carbon monoxide, and an ammonium sulphate fractionation of the proteins was carried out at 0° C. Most of the colourless muscle proteins and residual carboxy hæmoglobin were precipitated at 80 per cent saturation, and the carbon monoxide myoglobins were precipitated by raising the concentration of ammonium sulphate in the filtrate to 94 per cent saturation. The carbon monoxide myoglobins were dissolved with the minimum amount of distilled water and then dialysed against a citrate buffer, *p*H 5·70; sodium ion concentration, 0·34 gm. ions/l. An aliquot (20 ml.) of the myoglobin solution was subjected to chromatography on a column of 'Amberlite *IRC*-50', 16·5 cm. × 5·0 cm., with the citrate buffer as eluting liquid. The effluent from the column was collected in 3-ml. fractions and analysed photometrically at 278μ and 542μ. The result is shown in Fig. 1. The first band of protein to emerge from the column contained colourless proteins which had not been removed by the ammonium sulphate fractionation. This was followed by a band of hæmoprotein carbon monoxide myoglobin (*B*), which was almost completely separated from the main band of hæmoprotein carbon monoxide myoglobin (*A*). The main-fraction carbon monoxide myoglobin (*A*) behaved as a single substance when applied to a fresh column of the same resin and could be eluted from it quantitatively.

Table 1

Conc. of protein (gm./100 ml.)	Osmotic pressure (mm. mercury at 0° C.)	M/φ*	Molecular wt. (M)
0·43	3·99	18,326	18,551
0·51	4·72	18,548	18,822
0 64	5·93	18,228	18,563
1·01	9·54	18,029	18,559
1·46	14 20	17,464	18,211
1 51	14·72	17,415	18,188
		Average	18,482

* φ is a factor taken from measurements on hæmoglobin (ref. 4). External liquid, 0·03 M Na_2HPO_4 + 0 01 M NaH_2PO_4. *p*H 7·4 at 0° C.

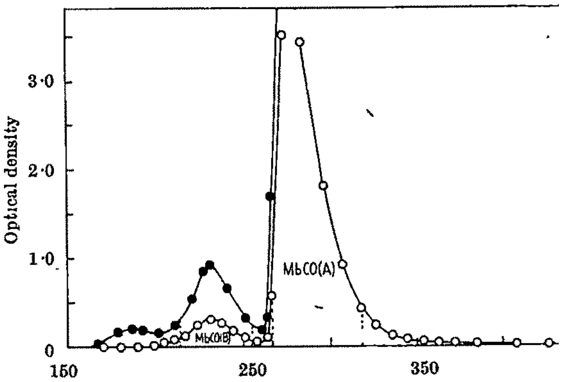

Fig 1. Chromatogram of a preparation of horse carbon monoxid myoglobin on a column of 'Amberlite *IRC*-50', 16 5 cm. × 5 0 cm Buffer citrate, *p*H 5 70, sodium ion concentration 0·34 gm. ions/l Rate of flow: 5–10 ml./hr. Temp. 2° C. Amount on column about 300 mgm. protein. ○, Optical density at 542μ; ●, optica density at 275μ

The dotted lines in Fig. 1 indicate the fractio collected as carbon monoxide myoglobin (*A*) ar carbon monoxide myoglobin (*B*). The absorpti spectra of the two proteins were identical in t visible and Soret regions; but the latter showed higher absorption at 275μ, indicating a higher tyrosi or tryptophan content. Examination in the 'Spinc ultracentrifuge showed that both preparations we homogeneous and they had similar sedimentati constants.

The molecular weight of the main-fraction carb monoxide myoglobin (*A*) was determined fro measurements of osmotic pressure, using the tolue osmometers of Adair[4]. Membranes which held abo 1·5 ml. protein solution were used, special care bei taken to make thin membranes which did not adso myoglobin. Concentrations of protein were calculat from refractometric measurements; but in certa cases these were checked by making cyanmetmy globin and measuring its absorption at 542μ. T extinction coefficient of a solution containing 1 mgm ml. of cyanmetmyoglobin (*E* 0·1 per cent) was fou to be 0·613.

The results of the osmotic pressure measureme are shown in Table 1. The figure obtained for t mean molecular weight of the main component w 18,400, which is considerably higher than the 16,8 obtained by Roche and Vieil[5] from osmotic pressu measurements and 17,200 obtained in ultracentrifu studies[6].

Moreover, the number of amino-acid residues per molecule calculated from the present amino-acid nalysis (Table 2) is greater than the number calulated by Tristram[7]. The present figures were btained from 24-hr. and 96-hr. hydrolysates (6 N ydrochloric acid under reflux) and corrections were made for the decomposition of certain amino-acids. When compared with Tristram's figures, it is seen hat there is an increase in the number of residues f leucine – *iso*leucine (4), phenylalanine (2), glycine 2), valine (1) and histidine (1) and a decrease of ne residue of serine.

A full account of these experiments will be published ater.

While this work was in progress, Theorell and keson[8] recorded an electrophoretic diagram for myoglobin showing three components. The main omponent, Mb 1, had an equivalent weight of 8,800, calculated from iron analyses, nearly equal o the molecular weight of our fraction MbCO*A*.

We thank Dr. D. A. Titchen for perfusion of horse earts. The amino-acid analysis was carried out by Ir. D. F. Elsden. This work, which forms part of he programme of the Food Investigation Organization of the Department of Scientific and Industrial Research, was carried out during the tenure by one f us (N. K. B.) of an I.C.I. fellowship.

An Extrarenal Effect of Pitressin

It is generally believed that the action of pitressin, nd more specifically, antidiuretic hormone, is ntirely referable to its effects on the kidney. Although n extrarenal site of action has been suggested, the vidence has not been convincing[1]. Our recent tudies in the rat suggested that pitressin might have n extrarenal action in this mammal[2]. This would gree with the findings in other vertebrate classes[3].

The problem was studied in the rat using inulin, s modified from the method of Ledingham[4], to measure extracellular fluid volume. The renal edicles were first ligated. One hour later, a measured mount of inulin was injected into the right femoral ein and two hours allowed for equilibration. At his time (0 min.), using light ether anæsthesia, a ·5-ml. sample of blood was obtained from the left emoral artery and analysed for inulin and sodium. his was followed immediately by the injection of I.U. of pitressin (Parke, Davis) in 0·5 ml. of saline ntraperitoneally in a group of ten animals. A control roup of ten received the saline only. A second lood sample was obtained 40 min. later from the ame artery. The procedure was repeated in fresh roups to cover intervals of 60, 90 and 120 min. after njection of pitressin.

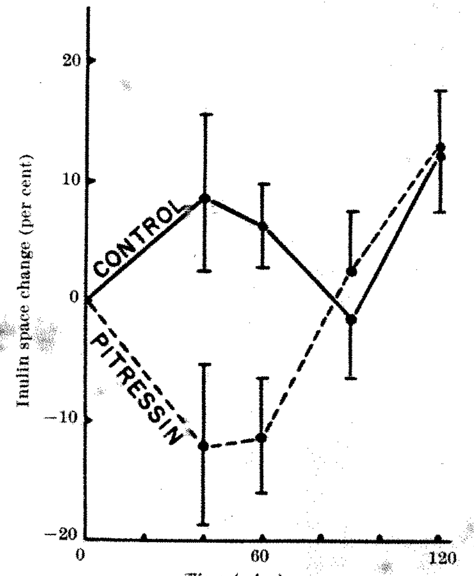

Fig. 1. Effect of 1 I.U. of pitressin intraperitoneally on inulin space in nephrectomized rats. Time of injection of pitressin is taken as 0, inulin having been injected 2 hr. previously to allow for equilibration

As shown in Fig. 1, pitressin caused a significant decrease in inulin space which can only signify a movement of water into the intracellular compartment. This was apparently accompanied isosmotically by sodium, since the plasma concentration of this ion remained unchanged throughout despite the decline in inulin space. In Table 1 the change in inulin space in two separate experiments is shown for the period of 60 min. after injection of pitressin.

Table 1. Effect of 1 I.U. of Pitressin on Inulin Space in Nephrectomized Rats

The first space determination, at 0 min., was carried out 2 hr. after inulin injection and was followed immediately by the injection of pitressin in the treated animals and saline in the control animals

	0 min.	60 min.	Change (per cent)

Secretory Potentials and Secretion in the Sublingual Gland of the Cat

INTRACELLULAR recording from sublingual gland cells in cats has revealed that the resting potential over the outer membrane is about 30 mV. (internal negativity). On repetitive stimulation of the chorda nerve, the potential difference increases to 50–60 mV., and this potential change is called a secretory potential[1].

When the tip of the electrode is inserted further through the gland cell, the tip penetrates the inner gland-cell membrane, and the resting potential of the lumen is found to be a few millivolts positive to the external medium. On activation, the initial potential change in the lumen is identical with the potential change in the interior of the gland cell. Thus the initial potential change is entirely over the outer cell membrane of the gland. With continued stimulation of the chorda nerve, a potential change usually, but not always, appears also over the inner membrane, its sign showing that the lumen becomes more positive to the interior of the gland cell.

For investigation of the mechanism of establishment of the secretory potential over the outer membrane, the secretory potential was investigated at different levels of membrane potential. For this purpose double-barrelled electrodes were used. After insertion through the outer membrane of the gland cell, the potential was measured with one channel and current flowed through the other. Fig. 1 shows that the secretory potential appears almost unchanged within a large range of membrane potential. Thus the secretory potential has no equilibrium potential. Hence it cannot be due mainly to a change in permeability but must be due to active transport. It is assumed that this transport is in the same direction as the secretory work, and to account for the sign of the potential it must be a transport of anions from the external medium to the interior of the gland cel over the outer membrane.

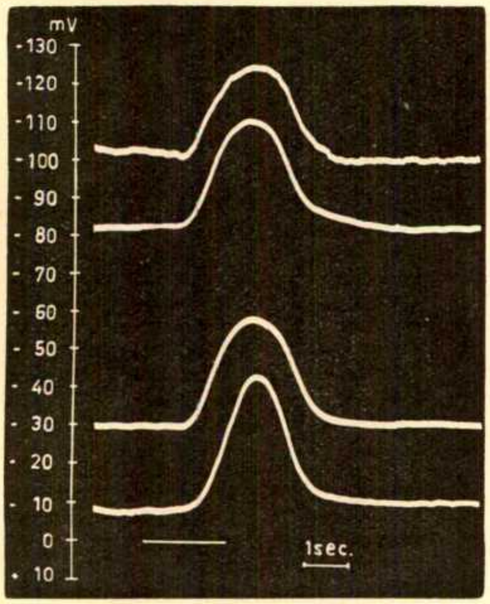

Fig. 1. Intracellular recording from sublingual gland cell with one channel of a double-barrelled electrode. Duration of repetitive stimulation of the chorda nerve at 25/sec. shown by white line. Record with a resting potential of 30 mV. was obtained without current flow through the other channel, and the remaining records with a current flow to change the 'resting' potential as seen in the figure (potential due to common coupling resistance subtracted)

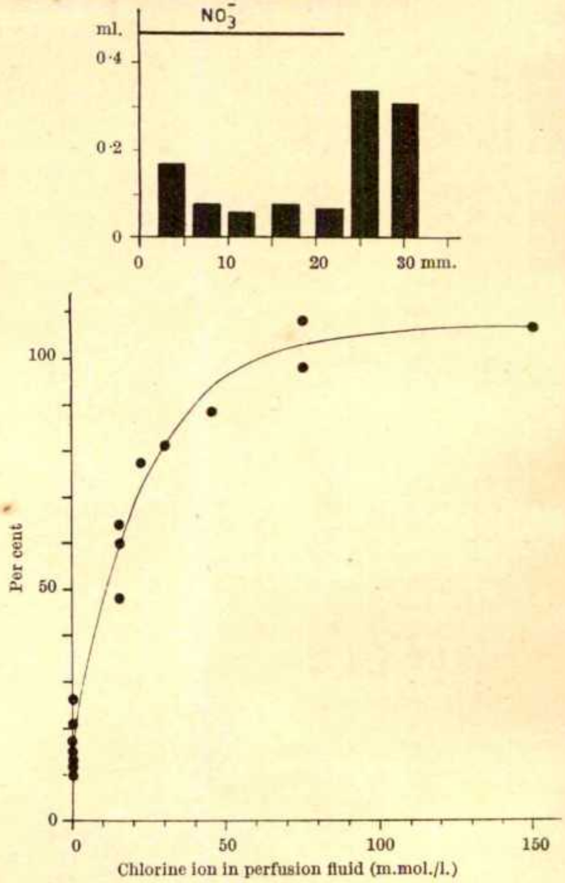

Fig. 2. In the upper plot each black column represents the amount of saliva obtained during 3 min. after injection of 1 μgm. acetylcholine. Horizontal black line shows duration of perfusion with chloride-free nitrate-saline; after 23 min., replacement with saline containing 150 m.mol./l. chloride. The graph shows the amount of secretion in response to 1 μgm. acetylcholine with partial substitution of chloride by nitrate in perfusion fluid. Ordinates, amount of secretion as percentage of that obtained in the same gland after change to a perfusion fluid containing 150 m.mol./l. chloride

This active transport of anions could account for secretion of salt and water; cations could follow due to electrical forces and water osmotically, and for passage through the inner membrane of the gland cell into the lumen of the tubulus the raised intracellular hydrostatic pressure might suffice. The sublingual gland saliva contains 160 m.mol./lit. chloride ion, and these ions are those that are transported if the secretory potential be the electrical sign of a transport responsible for secretion of salt and water. An active transport of chloride ions has been found in frog skin stimulated by adrenaline[2] and also in the frog gastric mucosa[3].

Further experiments have been made with glands perfused with oxygenated saline (at room temperature) containing physiological concentrations of sodium, potassium and calcium ions and with chloride as the only anion. On activation, such a gland gives a normal amount of secretion and the secretory potential over the outer membrane appears as in the blood-perfused gland.

On replacement of chloride ion in the perfusion fluid with nitrate ion the amount of secretion obtained on injection of 1 μgm. acetylcholine falls to 10–30 per nt (Fig. 2). The graph in Fig. 2 shows the amount secretion in response to 1 μgm. acetylcholine with rtial substitution of chloride by nitrate in the rfusion fluid. The amount is given as a percentage the amount of saliva obtained in the same gland er return to a perfusion fluid with full chloride ntent. It appears that with 10 per cent chloride e gland secretes 50–60 per cent of the normal nount, and with 50 per cent chloride the secretory sponse is virtually the same as with 100 per cent loride. These experiments show that nitrate ions e not toxic to the secretory process; the limiting ctor for secretion at low chloride concentration is ost probably depletion of chloride ions in the ternal medium of the gland cells (the amount of cretion in response to 1 μgm. acetylcholine at 100 per nt chloride ions is about one-fourth of the weight the gland).

In experiments with microelectrodes on the trate-perfused gland, a small potential change with e same sign as the normal secretory potential was countered over the outer membrane on activation. is therefore possible that this membrane has a nited capacity to transport nitrate ions, which ansport may account for the secretion remaining the nitrate-perfused gland.

Changes in the Dimensions of the Nuclei of Neurones with Activity

HYDEN[1] has summarized the evidence relating anges in cytoplasmic and nuclear constituents of e neurone to growth and activity of the cell. We ve found an increase in Feulgen staining in the urone nuclei of both the granular and molecular yers of the mouse cerebellum, following convulsions roduced by 'Picrotoxin' and 'Metrazol', as well as ter a fall[2]. The deoxyribonucleic acid content, measured by the specific absorptiometric technique[3], however, remained unchanged following a 'Picrotoxin' convulsion. These two findings suggested that an explanation of the apparent increase in Feulgen staining might be found in a contraction of the nuclei.

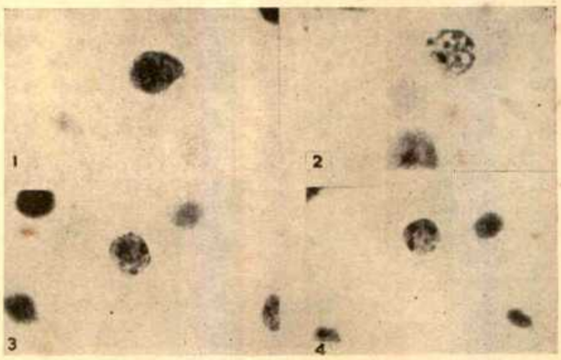

Fig. 1. Nuclei from the molecular layer of mouse cerebellum. (1) Resting mouse. (2) After running to exhaustion, 200 ft. in 10 min. (3) Convulsed with 'Picrotoxin', C.D.50. (4) Following a fall, 3 × 10 ft.

A change in dimensions of the nuclei was confirmed by direct measurement of the area of each nucleus. Freeze-dried samples of cerebellar tissue taken from the medial lobe by the method of Chance and Yaxley[4], after fixation in ethanol and embedding in paraffin wax, were cut transversely to the axis of the brain 15μ thick (since the average diameter of the nuclei of resting mice was 6·3μ) and stained with Harris's hæmatoxylin. Measurements were made only on whole nuclei at the periphery of the sample, where freeze-drying artefacts were absent. The area of a number of nuclei in five different parts of each section was measured; these measurements were repeated on sections from different mice receiving the same treatment (Table 1). The area of each nucleus was assessed in arbitrary units comprising the squares (to the nearest half-square) included in a camera lucida projection of the nucleus on to standard graph paper. These were then calibrated in μ^2.

This technique has been used for examining the changes in the dimensions of the nuclei of neurones of the molecular layer following the activities summarized in Table 1.

Table 1

Experimental details					Dimensions of nucleus viewed in transverse sections	
Activity of mouse	Severity of treatment	Time relations of treatment and sampling	No. of mice	Total No. of nuclei measured	Area (μ^2)	
					Mean	S.D.
1. Resting	—	—	5	116	26·95	6·74
2. Anæsthetized	'Seconal' A.D. 100 : 51 mgm./kgm. subcutaneous	Sampled while anæsthetized 15 min. after injection of 'Seconal'	5	120	22·74	5·66
3. Convulsed	'Metrazol' C.D. 50 : 20 mgm./kgm. intravenous	Sampled within 5 sec- of end of continuous clonic convulsion lasting not more than 30 sec. in each mouse	2	48	17·28	3·70
4. Convulsed	'Picrotoxin' C.D. 50 : 5 mgm./kgm. intravenous	Sampled within 5 sec. of end of intermittent convulsions lasting 5, 6 and 10 min.	2	49	17·52	11·58
5. Falling convulsion*	3 × 10 ft. fall	3 falls completed within 30 sec. Sampled within 5 sec. of last fall	5	125	10·91	3·35
6. Running	100 ft. in 5 min.	Sampled within 5 sec. of end of run	3	57	35·04	9·04
	To exhaustion. 200 ft. in 10 min.	Sampled within 5 sec. of end of run	3	70	37·33	12·48
7. Swimming	To exhaustion. 5, 10 and 12 min.	Sampled within 5 sec. of end of swim.	3	59	39·51	12·59

* See refs. 2 and 4.

Each treatment produced changes in the area of the nuclei, with confidence limits below 1 per cent, compared with nuclei from the resting mice. It is clear, therefore, that the different types of behaviour were reflected in changes in the dimensions of the nucleus, as assessed by the measurement of the area in transverse section. Although these changes probably reflect a change in volume, this is not certain in the absence of complementary measurements of the nuclei in sections cut longitudinally to the axis of the brain.

The standard deviation for each treatment group shows wide variation between treatments. It should be noted that whenever the activity includes periods of exhaustion ('Picrotoxin' induces intermittent seizures separated by periods of exhaustion), the variation is high. This could reflect the influence of recovery processes proceeding at different rates in each mouse, the different parts of the brain, or the separate nuclei. An analysis of variance revealed that only in the instance of swimming to exhaustion was there a significant difference between mice as well as a significant contribution to variance from parts of the brain (areas) and from area/mouse interaction. Significant differences between areas occurred in treatments 3 and 7, and area/mouse interactions were significant in 3 and 6.

The full details and analysis of results will be published elsewhere.

Action of Ascorbic Acid on Corticotropin

Holzbauer and Walter[1] have recently reported that the adrenal ascorbic acid – depleting properties of corticotropin are destroyed by treatment with ascorbic acid at room temperature for 18–20 hr. The corticotropin preparation used by these workers had a potency of 3 I.U./mgm. In view of the potential importance of their observation, we have repeated their experiment using highly purified corticotropin. The preparation used was a sample of corticotropin A_1 (for nomenclature, see Dixon and Stack-Dunne[2]), made in this laboratory by ion-exchange chromatography of an oxycellulose concentrate of pig corticotropin. This preparation had a potency of 110 I.U./mgm. when assayed by the adrenal ascorbic acid – depletion method of Sayers, Sayers and Woodbury[3].

A solution of corticotropin A_1 containing 0·4 I.U./ml. in Ringer solution, was divided into two portions. One portion was kept as control while ascorbic acid was added to the other portion to give a final concentration of 0·084 mgm./ml. Both solutions were kept for 18 hr. at 25°. These conditions and concentrations are identical with those of Holzbauer and Walter[1]. Both solutions were diluted for bioassay by the adrenal ascorbic acid – depletion method. The solution treated with ascorbic acid assayed 147 per cent of the control (p = 0·95, 76–282 p cent).

Our results are thus in contradiction to those Holzbauer and Walter. The increase in poten found is of doubtful significance, but could be e plained by the protective action of ascorbic ac against autoxidation of the hormone[4].

The difference in the observations is most probab explained by the low potency of the preparation us by Holzbauer and Walter. The ascorbic acid ma act by activation of proteolytic enzymes present the impure preparation. The presence of su enzymes in crude pituitary extracts has already be demonstrated[5].

It must be concluded, therefore, that ascorbic ac has no effect on purified preparations of corticotropi

Prof. Morris's results are in good agreement wit the observation of Holzbauer and Rigler[1] that th time necessary for the inactivation by ascorbic aci of the melanophore-expanding activity of pituitar extracts increased with increasing purity of th preparation. In these experiments, however, 88 pe cent of the melanophore activity disappeared i 28 hr. even when the activity of the preparation wa 150 I.U. of corticotropin per mgm. It is regrettabl that a highly active preparation was not availabl to us when the experiments with K. Walter wer carried out.

Reactions between Amino-Acids, Organic Acids and Sugars in Freeze-dried Apricots

Haas and Stadtman[1] separated an apricot concentrate (30 per cent solids) into cationic, anioni and neutral fractions and showed that brownin occurred when any two fractions were combined an stored at 57° C. The reactions of individual cations anions and neutral compounds in freeze-dried aprico *purée* stored at 25° C. and 70 per cent relative humidity (79 per cent solids) have now been studied After sixteen months, this material was a mid-brow colour. It contained 1-deoxy-1-(N-amino-acid) fructoses[2] and traces of 2-deoxy-2-(N-amino-acid) glucoses[3], together with sucrose, glucose and (traces of) fructose half-esters of malic and citric acids. These compounds replaced almost quantitatively the apparent losses of free amino-acids and malic and citric ids. After allowing for these reactions, there was loss of 11 m.moles of glucose and 8 m.moles fructose per 100 gm. fruit solids. It appears that, this relatively early stage of browning, the coloured ompounds were formed from sugars without the corporation of any significant amount of amino-id or organic acid residues. If the 1-deoxy-1-N-amino-acid)-fructoses were intermediates in brown-g, subsequent reactions must have included the lease of the amino-acid[4]. The behaviour of glucose-phosphate[5] suggests that the malic and citric id esters may also be important intermediates in rowning.

Equivalent quantities of apricot purée and browned eeze-dried *purée* were extracted with 80 per cent hanol. The soluble cations and anions were sep-ated by displacement chromatography on columns f sulphonated polystyrene[6] and 'Dowex-1-*X*4' in the cetate form[7]. The compounds were identified by eir order of emergence from the columns and by eir behaviour on paper chromatograms. Appro-riate fractions were combined for quantitative nalysis. The soluble neutral components were xamined and estimated by paper chromatography.

The amino-acids (as m.moles/100 gm. fruit solids) resent before and after browning were: asparagine 7·3, 1·3), aspartic acid (1·8, 1·0), proline (0·5, 0·5), lutamic acid, serine, alanine, γ-amino-butyric acid, hreonine, valine, glutamine, glycine, phenylalanine, ucine, pipecolic acid, and traces of tyrosine, histi-line, arginine and unknowns (1·8, 1·1). There was lso some ammonia (4·6, 4·1, estimated in the alcoholic xtract). After browning, at least twelve compounds *F*1–*F*11 and *X*1) emerged from the columns before spartic acid (total, 7·1 m.moles by weight, calculated s 1-deoxy-1-asparagino-fructose). In addition, at east six compounds (*Y*1–*Y*6) emerged between the mino-acids and ammonia (total, < 0·5 m.mole). Tests in solution and on paper indicated that *F*1–*F*11 were 1-deoxy-1-(N-amino-acid)-fructoses. The main omponent (*F*4) gave asparagine when heated with ·1 *N* acetic acid. Others gave aspartic acid, serine, hreonine, alanine and valine. *X*1 appeared to be 2-deoxy-2-asparagino-glucose, *Y*1–*Y*3 were 1-deoxy-amino-fructoses and *Y*4–*Y*6 were 2-deoxy-2-amino-glucoses.

The acids present (as m.moles/100 gm. fruit solids) before and after browning were: malic (50·5, 42), itric (9·8, 8·4), and small quantities of quinic, hosphoric, succinic and unknown acids. After rowning, some new acids emerged from the columns before and with quinic acid; hydrolytic experiments howed that they were sucrose, glucose and fructose alf-esters of malic acid (total, 6·5 m.moles). Similar sters of citric acid emerged just before malic acid total, 1·5 m.moles).

The neutral components found were sucrose (before rowning 100 m.moles; after, 67), glucose (79, 86), fructose (60, 80), xylose (1, < 0·5), a ketose oligo-saccharide, inositol, and sorbitol. Some sucrose 4 m.moles) was combined as esters, and it was assumed that 29 m.moles were hydrolysed to glucose and fructose. Approximately 1 m.mole of fructose and 11 m.moles of glucose were found combined in esters and amino-acid derivatives, leaving 8 m.moles of fructose and 11 m.moles of glucose not accounted for and presumably involved in the production of brown pigments.

Similar results have been obtained with freeze-dried peach *purée* stored under the same conditions for fifteen months.

This work, which will be reported fully elsewhere, was carried out as part of the research programme of the Division of Food Preservation and Transport of the Commonwealth Scientific and Industrial Research Organization, Australia.

The *Diego* Blood Factor in Chinese and Japanese

THE *Diego* blood factor was originally reported by Levine, Koch, McGee and Hill[1] in 1954, as a 'private' blood factor. A year later, studying the incidence of the *Diego* factor on Venezuelan subjects, we found[2] that it is relatively common in two stocks: 50 positive cases out of 170 Caribe Indians and 8 out of 152 Arawaco Indians. It was also present, although in low incidence, in people from Caracas and Barcelona (Venezuela) where Indian admixture was already known.

The serological independence of this factor from other blood factors was demonstrated by Levine, Robinson, Layrisse, Arends and Dominguez Sisco[3]. Its incidence has been studied by Junqueira *et al.*[4] in Carajás and Kaingangues Indians from Brazil, showing respectively 36 and 48 per cent of positives. Piaroa and Guahibo Indians living in Territorio Amazonas (Venezuela), who are anthropologically independent from all Indians mentioned above, also carry this antigen[5]. The Piaroas showed 3 *Diego* positive (12·5 per cent) out of 24 samples, and the Guahibos, 11 out of 76 (14·47 per cent).

Consistently negative results have been obtained in a thousand Caucasoids of the United States[3], two hundred random Dutch (van Loghem, personal communication), a hundred and fifty Spaniards and two hundred Italians (tested by us).

Since the Indians of the American continent are considered to be anthropologically related to the Mongoloid people of the Old World, we decided to investigate the incidence of the *Diego* factor in other available representative Mongoloids living in Venezuela. We now report our findings in Chinese subjects.

One hundred unrelated male Chinese from Canton (China), living in Venezuela, were selected for this study. Their physical features were typically Chinese and there was no admixture with the Venezuelan natives. The blood samples were tested against anti-Di^a serum by the indirect Coombs test as previously reported[2]. *Rh* factors (*C*, *c*, *D*, *E*), A_1A_2BO, *MN* and *Duffy* blood groups were tested by standard methods. Table 1 shows the results.

The frequencies of A_1A_2BO, *MN* and *Duffy* found in this study are very close to those already reported[6].

8	45	1	17	25	4	5·55	66·82	1·00	26·62	5	95	2·54	97·

As regards the *Rh* system, all but one were $Rh_0(D)$ positive. The *CDe* and *cDE* chromosomes have the incidence found by other investigators in Chinese[7]; the *CDE* chromosome was rather high (5·82 per cent) and the only Rh_0 negative found was a sample of phenotype *CCddee*.

The outstanding feature of this study was the detection of five *Diego*-positive Chinese (5 per cent). This finding indicates that the *Diego* factor is not restricted to South America. It indicates also that it could be present in all countries where Chinese have entered as part of the population.

The persistent absence of the *Diego* factor in all Caucasoids studied up to date and its presence in six South American Indian stocks and in Chinese suggest that this antigen is Mongoloid rather than Indian. It would not be surprising to find it in other Mongoloid branches.

The finding of the second sample of *Diego* antibody in a Polish couple, apparently unrelated to South American Indians, could not be explained before[3]. However, in the light of our findings in Mongoloids (Chinese and South American Indians), the presence of this antigen in a Polish family may be interpreted as indicative of Mongoloid admixture.

These facts indicate that besides its clinical importance (two cases of hæmolytic disease already known), the *Diego* blood antigen has a potential anthropological significance.

Dr. Albin Opalinski and Miss Abilia Rojas gave us technical assistance.

Subsequent to the submission of this manuscript for publication, we have studied sixty-five unrelated Japanese, finding eight *Diego* positives (12·30 per cent)[8].

The Blood Group Antigen *Diego* in North American Indians and in Japanese

THE blood group antigen *Diego* has been reporte to be present with not inconsiderable frequency i Indians of South America[1], but absent in 1,00 Caucasoids in the United States[2]. The secon example of anti-*Diego* was identified by Levine an Robinson (unpublished observation) in a specime submitted by Witebsky and Rosamilia. Using th latter serum, we have found the antigen *Diego* to b present in 16 of 148 unrelated Chippewa Indians i northern Minnesota, and 6 of 77 unrelated Japanes in Winnipeg. This suggests that *Diego* may be a Asiatic character. The family in which Witebsk and Rosamilia found anti-*Diego* was Polish, and w know from the frequency of the gene *B* that there i probably a somewhat greater admixture of Asiati blood in Poland than there is farther west in Europe The antigen *Diego* promises to be of great anthropological interest.

The Carotid Body of the Pilot Whale, *Globicephala melaena*

HEYMANS[1] has shown that mammalian blood pressure and respiration-rate are largely regulated by chemoreceptive cells which are innervated by the glossopharyngeal nerve. These are situated near the bifurcation of the common carotid artery (carotid body) and at the base of the great arteries (aortic body).

So far, no conclusions have been reached as to the ontogenetic relationship between receptor cells and their innervation. Some consider this system consists of two separate units[2]—mesodermal receptor cells which are eventually innervated—while others suggest a purely nervous organization in which receptor cells represent modified ganglion cells[3].

ısitivity to blood composition, as found in the otid body, would then be a function of nervous ;ue alone.

This latter view may find support in the present rk on the carotid body of the pilot whale. It was ısible to obtain fresh material from pilot whales ınded in Orkney during March 1955.

'he structure of the carotid body was found to 'er from those so far investigated in the intimate ıtionship between receptor cells and ganglion cells. ә presence of small numbers of scattered ganglion s, especially on the periphery of the carotid body, well known[4]. They usually occur singly and are all in size. By contrast, in the pilot whale, large umulations of compact masses of ganglionic tissue incorporated into the carotid body, amounting to sters of ten to twenty cells per 10μ section. These ıglion cells are identical in appearance with those nd in peripheral autonomic ganglia and they w the same variation in size and range of staining ction. The difference, however, lies in the fact t in many instances sinusoids, typical of chemoeptive tissues, are seen to ramify between the ıglion cells. In such cases the sinusoids are surnded by a few chemoreceptive cells, or by a body a large ganglion cell on one side, while chemoeptors lie close to the ganglion cell and the sinusoid. :h a modified ganglionic tissue is also frequently nd embedded in the branch of the glossopharyngeal ve as it approaches and penetrates the carotid ly. Indeed, those tissues occur more frequently ngside and in the vicinity of the nerve supply to carotid body than farther away from it, and as in s case the supplying nerve passes straight through carotid body, they often command a fairly central ;ition.

The carotid body of the pilot whale consists of ıumerable large and small lobes separated by con:tive tissue so as to form a rather diffuse organ. considerable variation is found in the structure of se lobes, which may contain chemoreceptive tissue, ıglionic tissue or a combination of the two in rying proportions. Often ganglion cells, bundles myelinated and unmyelinated fibres and chemoeptors are united into comparatively small glomeruli by well-developed connective tissue capsules (Fig. 1).

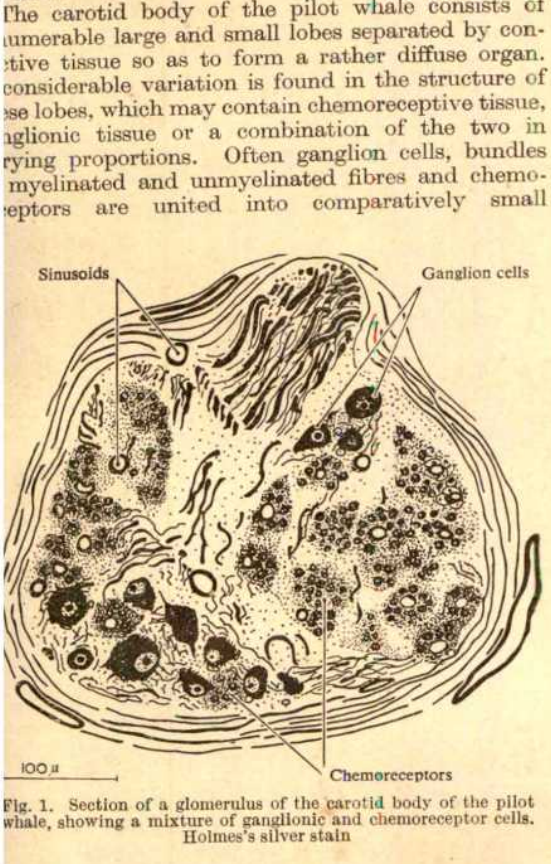

Fig. 1. Section of a glomerulus of the carotid body of the pilot whale, showing a mixture of ganglionic and chemoreceptor cells. Holmes's silver stain

It was found that the modifications of the carotid body of the pilot whale—one of the Odontoceti—are not shared by the Mystacoceti such as the finner whale, *Balaenoptera physalus*.

Detailed reports on both types of carotid body will be published elsewhere.

Separation of Epidermis from Dermis by Filtrates of *Trichophyton mentagrophytes*

Although fungi of the *Trichophyton* group have been shown to be capable of digesting keratin[1], little attention has been given to the possibility of their liberating toxic substances. As early as 1896, Macfadyen[2] showed that cultures of *T. tonsurans* liquefied gelatin by means of a diffusible enzyme, but this appears to have been overlooked in subsequent consideration of the pathology of dermatophytes. As part of an investigation into the pathogenicity of dermatophytes, studies have been made of the effects of filtrates of *T. mentagrophytes* upon skin. The fungus has been cultured upon a simple fluid medium which will also support the respiration of skin and exercise no toxic effects when portions of skin are 'cultured' in it for a period of five hours. The culture medium consisted of 12·9 ml. Krebs–Ringer phosphate, 1 ml. 10 per cent glucose, 1 ml. 2 per cent glycine, 1 ml. 1 per cent ammonium chloride and 0·05 ml. of a mixture of zinc sulphate, manganese sulphate and ferrous sulphate, each 1 mgm./ml. The constituent fluids were sterilized separately and mixed when cold. This amount of medium formed a shallow layer in a 20-fl. oz. screw-capped bottle laid flat.

A heavy inoculum of aerial mycelium from beer-wort agar cultures of *T. mentagrophytes* was added and incubated at 28° C. After fourteen days, the growth formed a mat over the surface of the fluid. Some slimy mycelial growth also occurred below the surface. The medium was then decanted and a fresh supply added. This was repeated at two fortnightly intervals. After this time the growth appeared to degenerate somewhat. The decanted fluid was sterilized by Seitz filtration and then stored at 0° C.

Tests for proteolytic activity were made by examining the effects of the filtrate upon dyed hide-powder ('Azocoll') and congo-red-fibrin. The former tests were made semi-quantitative by measuring the release of dye colorimetrically. In addition, the ability of the filtrate to liquefy gelatin and to hydrolyse salivary mucin was tested, the latter being carried out by the method of Sammons[3].

As commercial trypsin has been shown to cause separation of epidermis from dermis[4], portions of guinea pig ear skin were incubated with the filtrate in a similar manner.

In all tests two types of 'controls' were included—of uninoculated fungus medium and of boiled filtrate.

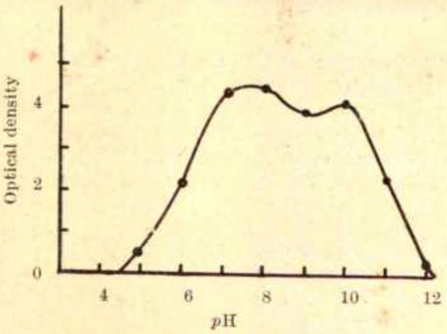

Fig. 1. The dye release from 'Azocoll' by filtrates of *T. mentagrophytes* in relation to *p*H

Release of dye from 'Azocoll' hide-powder was rapid—the undiluted filtrate showing activity within half an hour. Estimations of the release of dye over a range *p*H 4–12 indicate a wide range of activity from *p*H 6 to *p*H 11 (Fig. 1). There appeared, however, to be two maxima—about *p*H 7 and about *p*H 10. In repeat experiments the exact location of the peaks was not precise ; but the reduced activity between the maxima was always present. The experimental method, however, is not precise enough to define accurately the exact maxima.

The release of dye from congo-fibrin was considerably slower, at least four hours incubation being necessary. The range of *p*H over which activity appeared was similarly *p*H 6–11.

Sammons's test, which depends upon the ability of mucin to cause clumping of a suspension of barium sulphate, and the impairment of this property after enzymic digestion, also gave a positive result. Digestion of salivary mucus took place after about two hours.

Gelatin liquefaction occurred after incubation overnight, and similarly decolorization of denatured hæmoglobin was shown by allowing the enzyme to diffuse through a hæmoglobin-agar plate incubated at 37° overnight.

Finally, it was shown that incubation of thin slices of guinea pig ear skin with the filtrate so affected the epidermal–dermal bonds that the epidermis could be separated from the dermis by fine forceps. About two hours incubation was necessary, and this represents the time required for a solution of commercial trypsin 12·5 mgm./ml. to induce this loosening of the tissues.

Serum inhibited the skin-splitting effects of the filtrate and it also inhibited the hydrolysis of 'Azocoll' and hæmoglobin.

A filtrate from a culture of *T. rubrum* has also been examined and was found to have similar properties.

These results indicate that filtrates of *T. mentagrophytes* contain an enzyme or enzymes which are proteolytic. The wide *p*H range of activity and the two optima for the release of dye from 'Azocoll' suggest that more than one enzyme may be present.

The separation of epidermis from dermis by commercial trypsin has been stated to be due to the presence of an elastase[5]. We have found, however (unpublished observations), that a crystalline trypsin, although less effective, will also cause skin-splitting. The mucinase isolated by Sammons[3] will also split skin, and consequently this skin-splitting property gives indication of the nature of the protease prese

However, the knowledge that *T. mentagrophy* produces an enzyme which can cause separation epidermis from dermis throws some light on pathology of fungus infections. It is reasonable believe that, as the fungus grows in the more sup ficial layers of the epidermis, the proteolytic enzy diffuses from it and loosens the epidermal atta ments. Thus in areas exposed to friction, vesic will readily appear.

The proteolytic enzyme may be responsible for itching associated with epidermophytosis. Arth and Shelley[6] have shown that the injection of p teases into the skin is accompanied by itching.

Occurrence of Triple and Quadruple Cones in the Retina of the Minnow (*Phoxinus laevis*)

Triple cones have previously only been observ in the retinæ of a frog, *Rana temporaria*[1], and of gecko, *Aristelliger praesignis*[2], and in both the animals they are rare and atypical. I have examin many retinæ of trout, *Salmo trutta*, of all ages, a I have found a considerable number of triple con which, from their distribution in the cone patter appear to be anomalous double cones. In the minno however, triple cones are abundant and predomina in most regions of the retina, and quadruple con are numerous enough to suggest that they may ha a significant function.

These multiple cones are seen most clearly tangential sections of the retina (Fig. 1). In sever

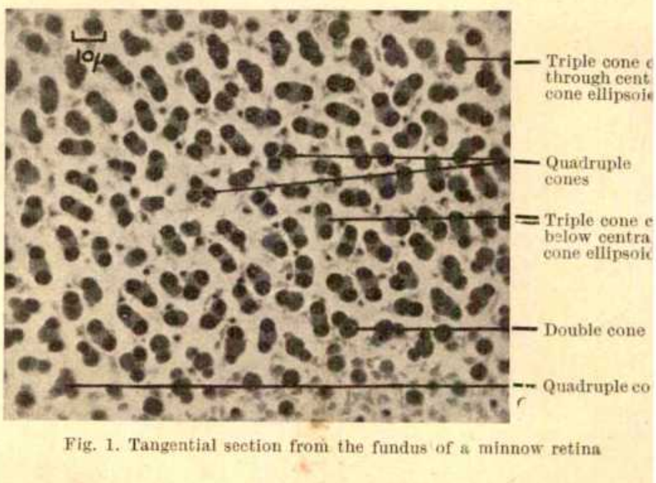

Fig. 1. Tangential section from the fundus of a minnow retina

tions the quadruple cones are proportionately re numerous than in Fig. 1. The three parts of a ut triple cone are of equal size ; but a minnow le cone consists of a large central cone with two aller cones arranged linearly on opposite sides of and a quadruple cone has three smaller cones ced symmetrically around the central cone. Each t of a multiple cone resembles a typical teleost gle cone in structure, having a small outer segment, rger inner segment with an ellipsoid, and a nucleus l foot-piece. In the minnow, the ellipsoid of the tral cone is level with the outer segments of the aller lateral cones, so that in a tangential section the ellipsoids of one multiple cone are not visible.

Site of Hibernation of a Tachinid Larva within its Host

DURING investigations on the physiological relations tween the pine looper, *Bupalus piniarius* L. (Lep. ometridae), and its parasite *Carcelia obesa* Zett. ipt. Tachinidae), some interesting facts were dis- vered, which so far as we know have not hitherto en described.

The egg of *Carcelia obesa*, which is deposited on e young caterpillar, contains a well-developed aggot which forces its way into the host within a w hours. Reaching the hæmocœl, the maggot eeps towards the head of the caterpillar and pene- ates into a mandibular muscle. (According to omp[1] the larvæ attach themselves first to the wall the fore-intestine.) The muscle reacts by the forma- n of a protruding hypertrophy, in which the resting aggot stays during the larval life of its host. *upalus* passes the winter in a state of pupal dia- use. When in the autumn the caterpillar pupates, d the mandibular muscles go into histolysis, the aggot (still in its first stage) is again released into e hæmocœl. However, when dissecting parasitized pæ in November and December, one finds the aggot mostly in a cavity between the abdomen and e wings, and consequently outside the body of the ture moth. This cavity not only contains exuvial id, but also a quantity of air which communicates th the first pair of abdominal stigmata, lying side the sclerotized pupal cuticle under the wing se. More than once we have taken the maggot the act of holding its caudal stigmata in contact th the air bubble.

Whether the maggot reaches the cavity actively, whether it is ejected by the host, is still being vestigated. The maggot resumes its development soon as diapause in its host is broken and adult velopment initiated.

Clearly the subalare air-mass of the host pupa is great importance to the hibernating parasite. The estion arises, What is its significance for the host elf ?

We have found air bubbles in the subalare cavity all pupæ of Lepidoptera so far examined : *Pieris assicae* L., *Sphinx ligustri* L., *Automeris io* Fabr., *ilosamia walkeri* Felder., and *Phalera bucephala* L. Only in *Pieris* and *Bupalus* did the air occupy the greater part of the cavity. In *Pieris* its volume may even exceed that of the abdomen. At first we thought this might be the clue to the intermittent release of considerable quantities of carbon dioxide during diapause by lepidopterous pupæ, as demonstrated by Punt[2], Schneidermann and Williams[3,4] and Buck[5]. However, the quantity of 'subalare air' was found to be relatively small in *Philosamia walkeri*, in which Schneidermann and Williams[4] have apparently found discontinuous respiration.

Most probably the air compensates for the loss of body water during the long period of hibernation, and thus provides a possibility of shrinking, which in the *pupa obtecta* is not otherwise provided for.

Observations on Pool and Capillary Feeding in *Aedes aegypti* (L.)

Gordon and Lumsden[1], in a classical paper, first directed attention to the fact that mosquitoes take up blood either directly from a capillary or from a pool formed in the tissues by the leakage of blood from a capillary previously lacerated by the mosquito's proboscis. The former method was termed 'capillary feeding' and the latter 'pool feeding'. It was also noted that, when a mosquito fed from a capillary, engorgement took about three minutes as compared with as long as ten minutes when the blood was taken by pool feeding. Attention was also directed to the significance of the two methods of feeding in relation to the taking up and deposition of pathogens by mosquitoes. These experiments were performed on the frog's web, using *Aedes aegypti* (L.), and were criticized[2] on the grounds that the mechanism of feeding might be very different in mammalian tissues. Recently, Griffiths and Gordon[3] developed a new technique for making observations on mosquitoes while they fed on the mouse's ear. Using this technique it was possible to show, by direct observation on living mammalian tissue, that no essential difference existed between the method used by mosquitoes while feeding on batrachian and mammalian tissues.

In view of the medical significance of these two types of feeding, it was considered of interest to determine the differences in the times taken by *A. aegypti* to engorge when feeding on man. It was hoped that such observations would indicate the frequency of the two types of feeding when man was host to the mosquito.

During the course of studies on the reactions of medical students to the bites of *Aedes aegypti* (L.)[4], records were kept of the time taken by each mosquito to fill to repletion (T_r). All observations were made at room temperature, which varied from 22° to 24° C. during the course of the observations. The mosquitoes all came from the same colony and had not had a

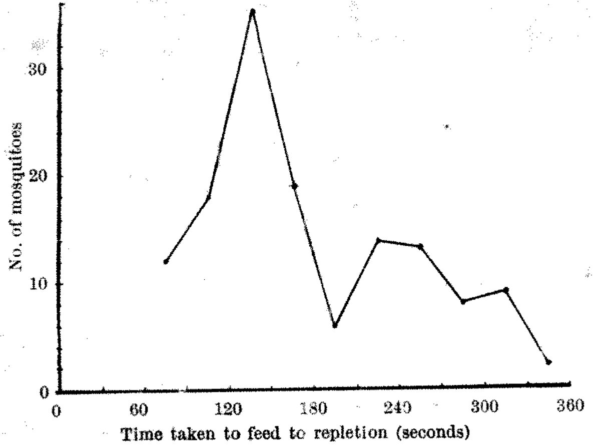

Fig. 1

previous blood meal. In all, 140 observations were made on seventy-five medical students, each observation being made on a separate mosquito. The time interval T_r was taken from the insertion of the proboscis to its final withdrawal after the mosquito had fed to repletion. Preliminary probings which ended by the proboscis being completely withdrawn and the mosquito failing to obtain blood were not included. Probing which did not result in the withdrawal of the proboscis but which was a preliminary to engorgement was included in the time T_r. The mean for T_r was 189 ± 77 sec. The results obtained are shown in Fig. 1.

The markedly bimodal distribution pattern of T_r shows that two groups occur in the population sampled. In the absence of other obvious differences between the mosquitoes used, it is reasonable to suggest that the two groups are capillary and pool feeders respectively. If we then assume that a mosquito feeding from a capillary takes 180–210 sec. as a maximum feeding time and that the pool feeders take at least 180 sec. to feed to repletion, we may then include the six specimens in the class 180–210 sec. with both groups. The mean time to repletion for capillary feeders then becomes 131 ± 33 sec. and for pool feeders 267 ± 50 sec. These means are highly significantly different when Students' T test is applied (P is less than 0·001). It will be noted that capillary feeding occurs more frequently than pool feeding, the latter method of feeding being used by about 40 per cent of *A. aegypti* feeding on man.

These results confirm Gordon and Lumsden's findings[1] and, although the direct observation in man of the two types of feeding is virtually impossible, show that there is strong evidence that the two types do occur. These observations were made while I was employed by the Unit of Veterinary and Medical Entomology, Science Service, Ottawa, Canada.

Effects of Gamma-(2 : 4-Dichlorophenoxy) butyric Acid on Sporelings of Bracken

AMONG their recent studies of the chemistry a mode of action of plant growth-substances, Wain a his co-workers[1] have demonstrated that a β-oxidati system exists in certain plants, whereby usua inert formulations of certain ω-phenoxyalkyl ca oxylic acids may be broken down in the plant the active acetic derivative. Since this is an enzyma reaction, there seems no reason why such oxidati should not take place in all classes of plants ; l the examples so far described belong to the Ang sperms. It is therefore of interest to note tl positive growth reactions have been shown by you plants of the common bracken fern (*Pteridi aquilinum*) when treated with γ-(2 : 4-dichlo phenoxy)butyric acid (2 : 4-D.B.).

During recent tests of the effects produced certain chemicals on 1-yr. bracken plants grow under garden conditions, three test plants were ea sprayed with 10·5 c.c. of a water solution of γ-(2 : dichlorophenoxy)butyric acid at a concentration 500 p.p.m. These plants (and others which were us as untreated controls) were chosen for uniformity frond growth, and each (in addition to a cent group of very small juvenile fronds, most of wh were short-lived) had sixteen to eighteen fronds 33–38 cm. height. Spraying was carried out August 9, and eight days after treatment two of t three treated plants showed epinastic curvatu on the stalks of the youngest, elongating fronds. Fo weeks after treatment, the plants were growi vigorously ; but many of the fronds showed epinas curvatures of the frond rachis and marked reducti in pinnule size. These fronds had a more rigid appea ance than those of the control plants, and the reduc pinnæ gave the experimental plants a delicate feathe appearance. Fronds developing later tended to ha more normal form ; but, for the rest of the seasc fronds on the treated plants showed a rather st erect habit.

At harvesting, seven weeks after treatment, three experimental plants showed vigorous fro growth, the number of fronds being greater than tl of the control plants. One of the treated plants w dug up, leaving the other two for future observatic The rhizome of this plant showed positive (growt regulating) reactions, the chief morphological featu being : (*a*) restriction of internodal developmer which resulted in the extension of the rhizome bei much less than that of untreated plants ; (*b*) mark contortions and dormancy of the majority of t rhizome apices ; and (*c*) increased root formati particularly around the dormant stem tips. As the case of frond growth, these morphological featur were less marked on the younger, later develope branches of the rhizome.

Such morphological features are all strictly in li with growth effects shown by young bracken plan when treated with the recognized active growt regulator, 2 : 4-dichlorophenoxyacetic acid (2 : 4-D In themselves, they do not prove the breakdown the butyric compound, and further analysis is need to show this. But the morphological reactions we marked enough to suggest that the butyric cor pound was degraded inside the plant to the mo active acetic homologue ; and that an oxidatic mechanism may operate in the tissues of the bracke sporophyte, at any rate in the early stages of develo ment.

Acknowledgment is made to the Agricultural search Council for its support of this work, and Messrs. May and Baker, who supplied samples of 2 : 4-dichlorophenoxy)butyric acid for testing.

Effect of the Anion on R_F Values of Quaternary Ammonium Salts

THE effect of anions on the R_F value of cations is most cases ignored, since little interaction has ever en found to exist. Pollard *et al.*[1] refer to the fferent R_F's of various cupric salts and also demonrate that lead, sodium and potassium move parately from their respective anions. Lederer[2] ates that butanol saturated with 0·5 N ammonium droxide keeps halide salts completely in the ionic rm and that they move as ions. Others[3] have noted fferent R_F's with several salts of acetylcholine.

While studying the *in vitro* metabolism of the nglionic blocking agent, 'Ecolid' chloride (4,5,6,7-trachloro-2-(2-dimethylaminoethyl)-*iso*indoline diethochloride)[4], we noticed that after precipitation tissue proteins with trichloracetic acid, paper romatograms of the acid solution yielded one spot ith R_F value 0·67, whereas 'Ecolid' chloride itself ve R_F 0·18. If, however, 'Ecolid' was precipitated ith reinecke salt and the reineckate chromatoaphed after treatment of the material at the origin ith silver nitrate to split the salt[5], a spot with R_F 0·23 sulted. A possible explanation for these phenomena that salts of 'Ecolid' migrate in undissociated form. herefore, the trichloracetic acid filtrate would give spot of 'Ecolid' trichloracetate whereas silver nitrate eatment of the reineckate would yield a spot of colid' nitrate.

To test this hypothesis, a solution of 'Ecolid' loride was passed through an anion exchange resin, ermutit S-2', and the 'Ecolid' hydroxide thus tained was added to various salt solutions. Aliquots these solutions were then subjected to ascending per chromatography along with the 'Ecolid' droxide using two solvents. Solvent A consisted n-butanol saturated with 0·1 N ammonium ydroxide, whereas solvent B consisted of 20 per nt ammonium hydroxide in 95 per cent ethanol. all cases identification of 'Ecolid' was by spray-g the chromatogram with a modified Dragendorff lution[5].

It is apparent from Table 1 that the nature of the nion markedly affects the R_F of the 'Ecolid' cation. he iodide and trichloracetate salts of 'Ecolid' are latively insoluble and crystals of each have been btained which are homogeneous by paper chromatoraphy. The iodide displays the same R_F as one repared by another route.

Shepherd and West[6] describe the appearance of a cond adrenaline-like spot in trichloracetic acid ltrates, which seems to be a complex of trichlorcetic acid and adrenaline. They suggest compound rmation between the weak phenolic group of drenaline and trichloracetic acid as the cause. imple salt formation between adrenaline cation and ichloracetic acid anion, similar to that observed with trichloracetic acid and 'Ecolid', could easily explain the effect observed by Shepherd and West.

Table 1

Anion	R_F of 'Ecolid™' in solvents A*	B*
Hydroxide	0·15–0·16	0·10–0·13
Fluoride	0·18	0·18–0·19
Chloride	0·18	0·45–0·5
Bromide	0·24	0·52–0·54

The effect of anions on the R_F of cations, in this case a bisquaternary ion, emphasizes that care must be taken in the interpretation of chromatograms from natural fluids or tissue extracts. The danger of loss of material due to the formation of relatively insoluble salts was underlined by our observation of a sparingly soluble 'Ecolid' trichloracetate in trichloracetic acid filtrate preparations. Therefore, standard solutions should not be prepared with simple solvents but with the fluid or tissue extract under consideration.

Arcs in Vacuum

DURING an investigation of the behaviour of electric arcs in vacuum, measurements have been made of arc voltages with various cathode materials, and photographs have been taken of cathode spot tracks on one particular material. Certain of these measurements may be relevant to phenomena occurring at the opening of low-current contacts in air.

To enable an arc to burn in a high vacuum, one electrode at least must vaporize. In all the tests made, the cathode provided the vapour from high current-density cathode spots.

Although the arcing voltages were exceedingly ragged, the average arcing voltage depended on the cathode material, as did the current necessary to maintain a stable arc. A solid cadmium cathode, for example, allowed a 2-amp. arc to burn steadily, whereas an arc with a tungsten cathode was unstable even at 50 amp. Oscillograph records showed no sign of a change of average arc voltage as an initially clean steel anode became coated with vapour from the cathode, and when cadmium was used as the cathode, heating the anode to a temperature above the boiling point of cadmium did not affect the average arcing voltage.

The anode was a flat steel disk about 2 in. in diameter, and pieces about ½ in. in diameter were used for cathodes, except in the cases of gold and nickel, when wires were used. The arcs, which were

Table 1

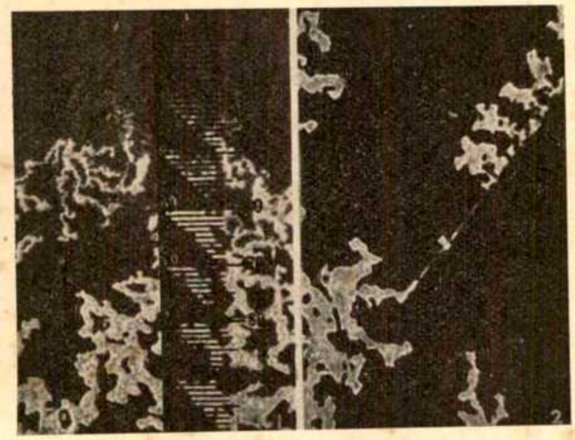
Cathode material	Arc voltage (volts)
Cadmium	10
Magnesium	12
Gold	12·5
Nickel	15·5
Silver	16·5
Aluminium	19·5
Carbon	20
Copper	21
Steel	33
Tungsten	>50

initiated by separating the electrodes, were drawn to lengths of between 1 and 10 mm.

The voltage gradient of the arc was less than 0·05 V./cm. in every case, and the arc voltage was very nearly independent of the arc current. Some arcing voltages are shown in Table 1.

After arcing had taken place, the cathodes all showed microscopic melting, with the exception of carbon, which had small pits burned into it.

If, instead of using a solid piece of metal for a cathode, a very thin film of metal evaporated on to glass is used, very clear cathode tracks can be obtained. Cathode tracks made by a 1-amp. arc about 2 cm. long on a film of cadmium about 0·02μ thick are shown in Figs. 1 and 2. In this case the arc was initiated by a spark from a third electrode. The narrowest track appeared to be about 0·4μ wide, which is about the same size as those caused by very short arcs on contacts, photographed by Germer and Boyle[1]. It seems likely that the wider tracks are made by the overlapping of narrower tracks, the cathode spots running around the edges of the tracks, and evaporating larger areas. That these cathode spots can be guided by fine scratches, like those shown by Germer and Boyle, is shown in Fig. 2. There is also evidence that the spot tracks become narrower where the metal film is thinner.



Photomicrographs (× 1,200) of cathode tracks on film of cadmium about 0·02μ thick. Current approximately 1 amp. (2) shows effect of very fine scratches guiding cathode spots

A detailed account of this investigation will be published elsewhere in due course. This communication is published by permission of the Director of the Electrical Research Association.

Formation of the High-Pressure Arc Column in Hydrogen

WE have noted[1] that by increasing the current a hydrogen high-pressure glow discharge betwe copper electrodes, we cause the discharge column concentrate gradually until a critical current value reached, when a sudden marked constriction occu resulting in a bright red column[2]. It was noted al that with clean electrodes, the characteristic glc discharge properties at the cathode are n affected by the column changes. We have now o served that similar effects may be obtained usi tungsten electrodes.

Our recent experiments give the variation of sor of the main properties of the column through t transition region, and typical results are shown Fig. 1. At low currents the column diameter increas slowly with current ; but between 1·0 and 1·5 am the column contracts gradually until at about 1 amp. a discontinuous constriction occurs, produci a sudden fall in the voltage gradient and a lar increase in the current density. The electrical a optical properties of the column are now almo identical with those of the normal hydrogen a Measurements of excitation temperatures of Balm series reveal that a minimum temperature is reach at the value of the constriction current, and th further increase in current produces increased te peratures and a convergence of the separate excitati curves. The results suggest that at low currents t excitation temperatures describe an electron ener

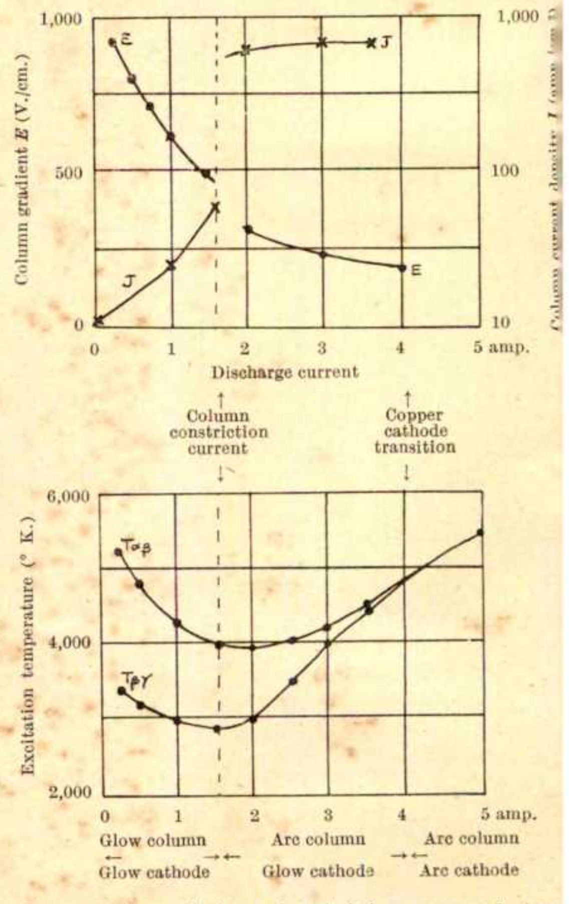

Fig. 1. Hydrogen discharge characteristics: pressure, 1 atmosphere; copper or tungsten electrodes; gap, 5–10 mm.

stribution, and that with increase of current the as temperature rises from a low value and approaches e electron temperature.

With both tungsten and copper electrodes further crease in current results in a discharge with normal rc cathode and column regions, with, however, o further discontinuous column changes. Thus may be concluded that the true hydrogen arc olumn is first formed when the sudden constriction ccurs. The experiments show also that the values r minimum excitation temperature are independent f pressure, gap-length and electrode material and lways occur at the constriction current. It seems kely, therefore, that the suggestions of King[3] are alid, namely, that the column constriction is ependent upon dissociation and thermal considera-ions. This view is further supported by our experi-ents, which show that with water-cooled copper lectrodes the constriction occurs at higher current alues if the gap distance is decreased, but that the everse effect is obtained with hot tungsten electrodes.

Aggregation of Spherical Particles

FESSLER[1] has recently directed attention to the xistence of pearl-string artefacts in random arrays f spherical glass particles, and suggests that the ccurrence of such arrangements in electron micro-raphs should be accepted with caution in the bsence of additional evidence. This communication lescribes a system in which this phenomenon has een observed using the electron microscope; but at he same time light-scattering measurements have lso confirmed the presence of associates of this hape.

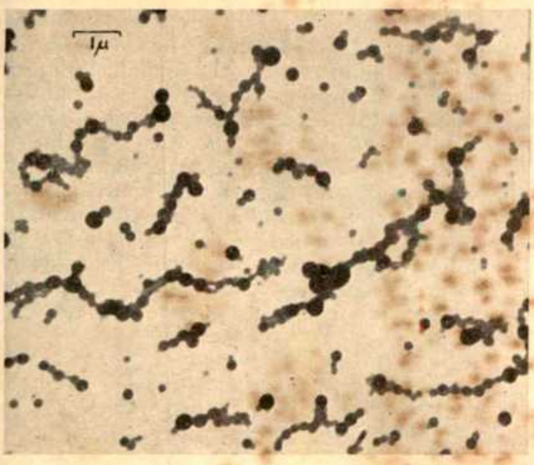

Fig. 1. Electron micrograph of precipitated polystyrene, showing small spherical particles and aggregates. × 11,000

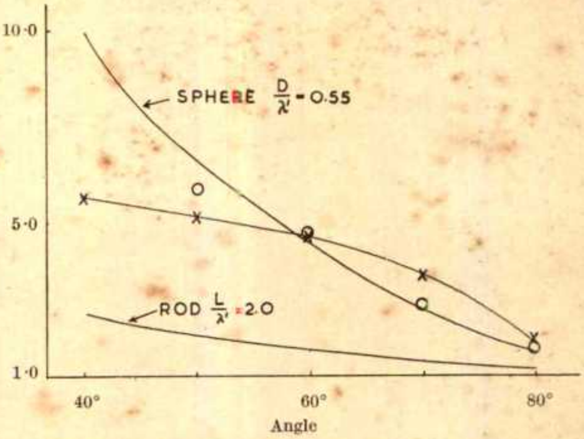

Fig. 2. Plot of dissymmetry against angle, showing the theoretical and experimental results. ○, Initial (5 per cent); ×, final (85 per cent) stages of precipitation

In the turbidimetric method of analysis of polymer solutions, non-solvent is slowly added to the solution, the turbidity being measured as the decrease in transmission of a parallel beam of light passed through the system. The method is useful for estimating the distribution of molecular weight, and also in detecting the presence of 'block' and 'graft' type polymers in the presence of their associated homo-polymers. The polymer is progressively precipitated, and if all this material is present in the form of spherical particles which are small compared with the wave-length of light used, then the decrease in transmission will give an exact measure of the quantity of each molecular species present in the system.

In an analysis of this type, a 0·004 gm./100 ml. solution of a sample prepared in the laboratory of polystyrene of molecular weight 400,000 was used. 30 ml. of this solution together with 12 ml. of methanol was placed in the turbidimeter cell at 25° C. and precipitation brought about by adding more methanol at the slow rate of 0·01 ml./min. with continuous slow stirring.

Electron micrographs of the precipitated material taken at the 50 per cent precipitation point (Fig. 1) show the existence of pearl-string associates. These are very large compared with the individual spheres also present.

Light-scattering measurements were also made on samples taken from the titration cell, the transference being carried out very carefully, in order to exclude contamination by extraneous particulate matter. Intensity measurements were made over the angular range, 40°–140° at 10° intervals, on samples of the initial (5 per cent) and final (85 per cent) stages of the precipitation.

Fig. 2 shows the dissymmetry of angular scattering at several angles. The dissymmetry is defined as the ratio of the intensity of scattering at the forward angle θ, to that at 180° − θ. Also in this figure are the expected distributions for spherical and rod-like particles of the size indicated, and calculated using the following relationships[2]:

$$P_{(\theta)} = \frac{3}{x^3}\,[\,(\sin x - x\cos x)\,]^2$$

$$P_{(\theta)} = \frac{1}{x}\int_0^{2x}\frac{\sin x}{x}\,\mathrm{d}x - \left(\frac{\sin x}{x}\right)^2$$

where λ' is wave-length of light in liquid, θ is angle of scattering ($\theta = 0$ for transmitted light), $x = \frac{2\pi D^*}{\lambda'} \sin \frac{\theta}{2}$, D^* being the characteristic dimension, D is diameter of the sphere and L is length of the rod.

In the early stages of the precipitation, the experimental points fall on the theoretical line associated with the spherical model. In the later stages the plot shows many of the characteristics of scattering expected of rod-like particles. This would be expected if the sample was a mixture of small spheres and linear aggregates of spherical particles. Work is proceeding in order to elucidate the problem further.

Latin-Square Designs with Individual Gradients in One Direction

THE efficacy of the Latin-square design[1] in eliminating two-dimensional variation from treatment comparisons, particularly in field experiments, has long been established. Kendall[2] states that horizontal and vertical gradients at least are removed from the comparisons, implying, of course, that the three degrees of freedom for columns in a 4 × 4 Latin square, for example, can be regarded as eliminating linear, quadratic and cubic components in one direction. The mathematical model for the analysis can be regarded equivalently as representing the background of the experimental material against which the experiment is conducted as a curved sheet, the curvatures in vertical planes parallel to the columns (rows) being equal for plots in one row (column). In some situations, however, the changes in the experimental material may be such that different curvatures are more realistic, and on the assumption that the more closely the imposed model represents the underlying phenomena, the greater the achievable accuracy, such alternatives merit consideration.

As usual, a completely general expression of the background material introduces difficulties because of the relation between the number of parameters estimated and the number of degrees of freedom for error, so that some compromise guided by *a priori* knowledge is required, and only the simplest cases have so far been studied.

In one case, for which applications can immediately be envisaged (see below), it is assumed that columns (say) are discrete and that variation within them may be represented in terms of individual linear regressions. The mathematical model used therefore is:

$$y_{ij} = \mu + \varkappa_j + \beta_j a_{ij} + \theta_i + e_{ij}$$

where y_{ij} is the observed value for the experimental unit of the ith treatment in the jth column; μ is the general mean; $\varkappa_j$ and β_j are the location and slope parameters for the linear variation in the jth column; a_{ij} is the discrete row constant for the ith treatment in the jth row measured from a zero mea at the centre of the rows, and it is convenient to tak

$$\sum_{i=1}^{n} a^2_{ij} = \sum_{j=1}^{n} a^2_{ij} = n\,;$$

θ_i is the ith treatment parameter.

As usual, it is assumed that the unexplaine variate e_{ij} is distributed normally and homoscedastically with variance σ^2 about a zero mean.

Unbiased estimates of treatment comparisons ca readily be obtained, and the variance – covarianc matrix for an $n \times n$ Latin square is

$$-\,n\,[\mathbf{AA}' - n^2]^{-1}$$

where $[\mathbf{A}]$ is the matrix $[a_{ij}]$.

The linearly declining portions of the lactatio curves of dairy cattle and goats form the background for numerous experiments, in some of which treatmen after-effects are absent or sufficiently small to perm the application of the preceding analysis. Th corresponding analysis of variance on the left i Table 1 is compared with the conventional analysi of a randomization imposed on the lactation curve of four Guernsey cows.

Table 1. ANALYSES OF VARIANCE OF MILK YIELDS (LB./WEEK)

Gradient	d.f.	m.s.	Conventional	d.f.	m.s.
Cows	3	8,525·4518	Cows	3	8,525·451
Regressions ignoring treatments	4	553·3383	Weeks	3	398·701
Treatments adjusted for regressions	3	35·5477	Treatments	3	86·097
Unexplained variation	5	39·5352	Unexplained variation	6	177·212

The treatment estimates for the two methods are

	$\hat{\theta}_1$	$\hat{\theta}_2$	$\hat{\theta}_3$	$\hat{\theta}_4$
Gradient analysis	−4·97	1·07	0·83	3·0
Conventional analysis	0·55	−2·02	−4·70	6·1

The variance – covariance matrix for the design usec is:

$$\frac{1}{8}\begin{bmatrix} 3 & 0 & -1 & 0 \\ 0 & 3 & 0 & -1 \\ -1 & 0 & 3 & 0 \\ 0 & -1 & 0 & 3 \end{bmatrix}$$

so that the variance estimate for differences betwee two treatments is either 39·54 or 29·65; compariso with the corresponding estimate, 88·61, obtaine from the conventional analysis shows that in thi case a substantial increase in the amount of information has been achieved. The greatest increases i information may be expected when large difference exist between the individual regression coefficients a situation more likely to occur in animal than i crop experiments, and the gradient analysis may b especially useful when animals from a small her cannot easily be matched for stage of lactation.

A detailed paper, on the methods discussed her and on the general case allowing for higher-orde individual regression terms, is in preparation.

Thursday, June 14—Friday, June 15

ciety for the Study of Fertility (on Thursday at the Meeting se of the Zoological Society of London, Regent's Park, London, .1, and on Friday at the National Institute for Medical Research, Hill, London), at 10 a m. daily—Conference.

Friday, June 15

yal Institution (at 21 Albemarle Street, London, W.1), at n.—Sir Gavin de Beer, F.R.S. "Archæopteryx".

APPOINTMENTS VACANT

plications are invited for the following appointments on or re the dates mentioned:

sistant (scientist with experience in initiating projects and dinating the work of research teams under a pre-determined ramme) to the Director of Research—The Director of Re- h, British Food Manufacturing Industries Research Association, dalls Road, Leatherhead, Surrey, marking envelope "Confidential" e 13)

emist (with a first- or good second-class honours degree or valent qualification, at least three years experience, and preferably owledge of liquid fuels and lubricants) in the Central Laboratory, wick—Recruitment and Training Officer (F/EV.. 587), London sport, 55 Broadway, London, S W.1 (June 14).

sistant, Grade B, in the Physics Department; and an stant, Grade B, to teach Biology in the Natural Science De- ment—The Principal, Derby and District College of Technology, nanton Road, Derby (June 16).

search Fellow in Chemistry to carry out original work on a chemical topic in the Londonderry Laboratory for Radio- nistry; and a Research Student in Radiochemistry, to under- original research leading to a higher degree—The Secretary, University, 38 North Bailey, Durham (June 16).

esearch Assistant in Mathematical Statistics; and a earch Assistant in Numerical Analysis—The Registrar, The versity, Liverpool (June 18).

ssistant Lecturer or Lecturer in Zoology—The Secretary Registrar, The University, Southampton (June 20)

ecturer in Applied Mathematics—The Secretary, The Univer- , 38 North Bailey, Durham (June 20).

ecturer in Pure Mathematics—The Secretary, The Queen's versity, Belfast (June 20)

esearch Fellow (graduate, with experience in natural products aistry) in Chemistry, at the University College of the Gold Coast he Secretary, Inter-University Council for Higher Education rseas, 29 Woburn Square, London, W.C.1 (June 22)

nglish Electric Company Research Fellow in Aeronautics he Secretary of University Court, The University, Glasgow. ne 23).

xperimental Officer (agricultural graduate or person with parable qualifications) at the Dunholme Field Station, Lincoln, ssist in experiments on sugar beet—The Secretary, Rothamsted erimental Station, Harpenden, Herts (June 23).

entific Officer (with a knowledge of advanced chemistry and graduate training in plant physiology) in the Department of nt Breeding, to study developmental physiology of fruit trees, particular reference to growth and flowering hormones—The etary, John Innes Horticultural Institution, Bayfordbury, Hert- , Herts (June 23).

Research Assistant in Psychology—The Secretary, The University, 38 North Bailey, Durham (June 25)

Research Fellow (graduate with teaching and/or research experience) in Education—The Registrar, The University, Bristol (June 25).

Assistant in Parasitology—The Assistant Secretary, The University, Edinburgh (June 30).

Lecturer in Physical Geography; and a Lecturer in Economic Geography, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C 1 (June 30).

Lecturer (with special qualifications in physical and/or inorganic chemistry) in Chemistry in St. Salvator's College—The Joint Clerk to the University Court, College Gate, St. Andrews (June 30).

Lecturers (3) in Microbiology—The Registrar, The University, Birmingham (June 30).

Senior Lecturer or Lecturer (with a degree or equivalent qualification in veterinary medicine) in Animal Health, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 3).

Research Officer or Senior Research Officer (with a university honours degree in science with chemistry as a major subject, postgraduate research experience, and preferably experience in paint technology) in the Division of Building Research, Commonwealth Scientific and Industrial Research Organization, Highett (near Melbourne), Victoria, Australia, to co-operate with another research officer who will be making a study of the chemical and physical characteristics of fibrous plaster—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 390/238 (July 7).

Lecturer in Electrical Engineering; Lecturer in Civil Engineering, and a Lecturer in Mechanical Engineering—The Assistant Secretary, The University, Edinburgh (July 9)

Lecturer in Statistics—The Registrar, The University, Hull (July 11).

Lecturer in Mathematics at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 15).

Lecturer (with an honours degree and experience in research or in clinical work) in Psychology, at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 15).

Fellow (with an honours degree of a British university) in Physics—The Warden, Merton College, Oxford (July 23)

Assistant Keeper in the Department of Geology; and an Assistant Keeper in the Department of Archæology—The Secretary, National Museum of Wales, Cardiff (July 28).

Lecturer in Mathematics at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 31).

Lecturer in the Department of Psychology, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (New Zealand, July 31)

Lecturer (university graduate in civil engineering and preferably some professional experience, and a specialized knowledge in the theory of structures) in Civil Engineering, at Auckland University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31)

Lecturers or Senior Lecturers (2) in the Faculty of Rural Science, one in Physiology and one in Biochemistry, at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1 (Australia, July 31).

Assistant (with good academic qualifications and experience in the organization of work programmes at a large industrial laboratory) to the Divisional Chief Scientist, West Midlands Division—Divisional Establishment Officer, National Coal Board, Himley Hall, Dudley, Worcs.

Biochemist (recent graduate) in the Department of Clinical Research, to assist in a research programme relating to certain biochemical aspects of mental illness—The Physician Superintendent, Crichton Royal Mental Hospital, Dumfries.

Conservation Officers (under 30, with a degree in agriculture, agricultural engineering, conservation or pure science; or obtain such a degree in June–July) in the Department of Conservation and Extension, Ministry of Agriculture, Federation of Rhodesia and Nyasaland, for duties which will consist of advisory work among farmers on all aspects of agricultural production as well as the conservation and utilization of the soil—Federal Public Service Attaché, Rhodesia House, 429 Strand, London, W.C.2.

Demonstrator or Assistant Lecturer in Botany in the Department of Biological Sciences—The Registrar, Wye College, near Ashford, Kent.

Demonstrators in (*a*) Agricultural Botany (preferably with an interest in plant physiology); (*b*) Microbiology (with an interest in dairying or soil microbiology); (*c*) Agricultural Chemistry (with qualifications in agricultural chemistry); and (*d*) Agricultural Zoology (with qualifications in agricultural zoology or zoology)—The Registrar, The University Nottingham.

Experimental Officer (male, with a degree in engineering or physics or H.N.C. in electrical or mechanical engineering, or equivalent qualifications, and experience in instrumentation, especially servo mechanisms or computing, and preferably a knowledge of guided weapon control techniques), at the Royal Military College of Science, Shrivenham, Berkshire—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. D.38/6A.

Geneticist, Scientific Officer grade (with some research experience and an interest in quantitative genetics), to work with mice on problems related to animal breeding—The Director, Institute of Animal Genetics, West Mains Road, Edinburgh 9.

Laboratory Technician (Zoology) (with some knowledge of biological techniques and/or experience in the use of laboratory apparatus)—The Registrar (ZT), Queen Mary College (University of London), Mile End Road, London, E 1.

Lecturer (preferably honours graduate with industrial experience) in Inorganic Chemistry—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

Lecturer (with a good degree, and preferably industrial experience) in Metallurgy—The Secretary, Royal Technical College, Glasgow.

Non-Medical Biochemist, Basic grade (with a university degree in biochemistry or A.R.I.C.), to work under the Consultant Biochemist—The Hospital Secretary, Paddington General Hospital and Group Laboratory, Harrow Road, London, W.9.

Research Assistant (female, with a degree in chemistry or physics, and an interest in the physical chemistry of biological systems)—The Secretary, The Research Institute (Animal Virus Diseases), Pirbright, Surrey.

Research Assistant (Ph.D. standard), for work on the physical absorption of vapours on ionic crystals—Dr. F. C Tompkins, F.R.S., Imperial College of Science and Technology, London, S.W.7.

Research Lecturer or Assistant Lecturer in Statistics—The Registrar, The University, Nottingham.

Research Students to work on problems relating to atmospherics—Meteorology Section, Cavendish Laboratory, Cambridge.

Scientific Officer (with a first- or second-class honours degree) for laboratory work on physical and engineering problems associated with the use of new techniques in crop conservation—The Secretary, National Institute of Agricultural Engineering, Wrest Park, Silsoe, Beds.

Senior Lecturer or Lecturer (with a special interest in inorganic chemistry) in Chemistry, at the University College of Khartoum, Sudan—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Senior Technical Assistant for development work in the Bacteriological Laboratory—Prof. Todd, Royal Technical College, Glasgow.

Student Technician (male or female) in the Pathological Laboratory—The Secretary, Wembley Hospital, Wembley, Middlesex.

Superintendent Physicist (with high qualifications in physics and a wide experience of explosive shock phenomena, and preferably some experience in the study of transient electrical phenomena), to lead a team in the study of shock excitation of materials to high temperatures—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. No. 1141/34.

THERMAL POWER FROM NUCLEAR REACTORS

by

A. Stanley Thompson and Oliver E. Rodgers

Size: 9½ *in.* × 6 *in.* 242 *pages* *Illustrated* 58*s. net*

A study of the application of engineering principles to nuclear reactor design. Written from a mechanical engineer's viewpoint and stressing a design approach, the work discusses problems of reactor development which confront the engineer in atomic power plants. The introductory chapters give a concise review of nuclear fission and a general description of nuclear reactors, helpful in orienting the engineer to current thought of physicists.

ESSAYS IN BIOCHEMISTRY

Edited by

Samuel Graff

Size: 9½ *in.* × 6 *in.* 355 *pages* *Illustrated* 52*s net*

These essays were written in honour of Hans Thatcher Clarke, on the occasion of his retirement as Professor and Chairman of the Department of Biochemistry, College of Physicians and Surgeons, Columbia University. They survey the present status of biochemistry, discuss major research problems, and speculate on future trends.

THE BALANCE OF ARTS AND SCIENCES IN EDUCATION

PEAKING at the North-western Management Conference at Southport on March 19 of the need industry for students of the humanities, Mr. R. O. Thomas urged that, to meet the advances science and technology, and changes in the tech- que of control and communication which electronics bringing about, we need men who are responsive ideas over a wide front and who are capable and ady to accept responsibility with courage and cision. Without such men who can appreciate entific method and the nature of scientific ideas well as the humanities, efficient organization and ministration are scarcely possible to-day ; nor are likely to deploy to the best advantage our present nited numbers of scientists, technologists and tech- cians, let alone achieve the larger number that Great itain requires. Whether, like Mr. Thomas, we are imarily concerned with the training of managers, , like Dr. D. S. Anderson, addressing the Northern unties Technical Examinations Council, our con- rn is chiefly with the expansion of the technical lleges and colleges of technology, or whether our ncern is with the shortage of scientists or the nction of the universities in this age of nuclear wer and the electronic computer, we are brought ce to face with the question of general education d the need for a balance between science and the manities, both in the training of the scientist and chnologist and in that of the administrator and an of affairs.

This is indeed the central problem which has to be ced in planning the expansion of university and chnological education as well as of technical ucation, and no allocation of resources of materials d finance which ignores it will suffice. We have to ake up our minds what we mean by general lucation in this context—how and where it should given—and not merely formulate adequate pro- sals but also take effective measures to give effect them. It is idle to hope that the situation will nprove of itself. It is more likely to deteriorate. ven from the point of view of science alone, Dr. obert Oppenheimer, speaking to the American stitute of Physics on February 2, expressed the iew that the pioneer conceptions which led through instein to the splitting of the atom are now in- lequate to yield an orderly description of the ysical world. Dr. Oppenheimer is not confident at the man or woman who can rescue us from the ch disorder of our new knowledge will speedily ppear ; but he believes that he or she is likely to be young natural scientist. It is even more probable at he or she will be someone able not merely to terpret the nuclear scientist to fellow natural ientists, but equally to set that new knowledge in e context of biological science and of the humanities.

It is important, therefore, that full support should e given to what is already being done in Britain to ncourage movement or transfer from the arts side science, both on the part of those just leaving school and also within the university. The fifty scholarships endowed by Imperial Chemical Industries, Ltd., for those leaving school who wish to transfer from the humanities and enter the universities to train as scientists is a welcome step ; but it is an example which needs to be followed by the universities themselves, as well as by the Ministry of Education and the local authorities. For a time it will only touch the fringe of one problem ; but it could demonstrate the value of such a transfer, and the cumulative effect may be invaluable. It is no substitute, however, for the fundamental thought about the content of courses and balance of studies, the hard work that may be involved in replanning complicated time-tables and the fundamental questions as to the respective purpose or functions of university, college of technology and technical college.

That challenge is, however, already being met. Sir Eric Ashby and Prof. K. Denbigh have recently directed attention to the place of the humanities in technology and suggested that technology can, in fact, be taught as an essential element in a liberal education and one which makes for social coherence. Pointing out that human interests and sympathies are even more to be desired in the technologist than in scientific workers in the laboratory, Prof. Denbigh has stressed the real need to-day for technologists who are good at their speciality but who have an equal interest in management, and emphasized that because of his human responsibilities and contacts the technologist needs imagination and something of the outlook of the humanist. He puts the intellectual value of technology rather with that of economics, psychology or medicine, and suggests that, rightly presented, it should appeal to the boy or girl whose school work is in the humanities. Still more recently, Prof. C. W. Dannatt, in his presidential address to the Institution of Mining and Metallurgy on May 17, in discussing the educational value of technological studies, claimed that they provide the discipline and training essential to culture ; but he indicated also the problems that require attention if they are to develop that full educational value.

The demonstrable value of the humanities, properly taught, to the future administrator should make us take care that the administrator of to-day, in acquiring the understanding of science and technology that he needs, preserves that element ; but equally the scientist intended for managerial responsibilities should be given full opportunity of acquiring it. Here, as Prof. Denbigh points out, there is room for more constructive thought about the assimilation of technology into the social structure. Training for leadership bears closely on leadership in a technological society, and the problems of technological change and the adaptation of society to innovation.

If, however, any considerable changes are to be made in the content and balance of university and technical college courses, there must be widespread public understanding of the reason for those changes. The Government has indeed recognized in the White Paper on Technical Education that, without the support and understanding of parents, we can scarcely expect to obtain the considerable increase in the number of students of technology that is required. This is no less true of any increase in the number of scientists, and the growing dependence of the universities on public support makes it essential in regard to changes of policy. The academic freedom and autonomy of a university can only be preserved if their importance is clearly understood by those from whom ultimately its resources are mainly drawn.

This is one reason for welcoming the further number of *The Twentieth Century* devoted to the universities, which appeared in February. Although this issue was concerned solely with the so-called civic universities, it is well calculated to further the public understanding and the respect for learning and pursuit of truth by the governing elements in Britain which are the ultimate guarantee of academic freedom in any society. Moreover, the symposium is far from being a survey and comparison of the provincial universities: their weaknesses as well as their achievements are assessed, and many points are indicated on which searching inquiry as well as constructive thinking should be proceeding if the universities are to make their fitting contribution to the expansion of technological education or in meeting the needs of the increased number of those leaving school which will be seeking admission in the next ten years.

Principal P. S. Noble, for example, who is confident that, despite increasing dependence on government support, academic freedom is not seriously endangered because the mutual understanding and respect between the universities and governing circles is likely to continue, points out that economic conditions will none the less determine whether we can continue to expand facilities and maintain standards. Nor can we yet assume without question that there is a considerable untapped reservoir of talent, or that there is not already in the universities of Britain at the public charge a considerable number of students who for lack of ability or other reasons are unfitted for university education. Indeed, Prof. J. Simmons is frankly dubious on this point. He does not believe that the standard of ability is declining; but he considers that students enter universities less well prepared than in the past, less widely read and often inadequately grounded in such fundamentals as the use of the English language. This, Prof. Simmons remarks, wherever the responsibility lies, tends to lower the standards of university teaching; and he sees another and more insidious threat to academic standards in the tendency of some students to regard as of right—not as a privilege to be earned—the assistance which some three-quarters of university students in Britain now receive in one way or another from public funds. Such an attitude may well prevent the student from deriving the full advantage of a university education, and quite apart from its inhibiting effect on the effort he puts into his studies, it may well blind the stude as to the real purpose of a university education.

That at least is something which needs to be mc clearly and generally understood, not merely by t student but also and more especially by those cc cerned with the planning of university expansic and not least when that expansion is being cc sidered in relation to some particular need such technology. This symposium throws little light that purpose. Prof. Simmons reminds us that t advancement of learning is the central task of universities, and he is clearly concerned that ove anxiety to raise the standards of teaching may le the civic universities to press their teachers so ha as to hinder the continuation of the notable co tribution to learning which, collectively, they ha made.

Prof. Simmons's uneasiness is reflected in Arnc Kettle's impressions of Leeds. He, too, comments the comparative illiteracy which often characteriz first-year students in their inability to write cohere sentences, to read with pleasure a good book an their ignorance of history. An appreciable proporti of successful scholarship candidates, he maintair are intellectually ruined by the process of crammir and pseudo-specialization which the present schola ship system induces in the grammar schools. B his statement that, in the only provincial universi he knows well, probably most of the students a completely lacking in intellectual interest is not ju depressing; it is as much an indictment of tl teaching as an indication that students are unfitte for a university course. Mr. Kettle's impressions a undoubtedly disturbing. He doubts whether tl provincial universities of Britain are yet in any real valuable sense civic or regional universities, and l has some comments on the tendency to stress t technological and vocational aspects of universi education which are highly pertinent to the prese discussion on the expansion of technical educatio We can only impart to our students the broa mindedness that is so desirable by teaching any ar every subject from a fully humane and non-dogmat point of view with sufficient emphasis on its origin purposes and implications.

Nor is Mr. Kettle the only contributor who fea that the provincial universities are at present gre purveyors of the mediocre. The symposium as whole suggests that there is a good deal of disqui as to conditions and standards, of which note shou be taken before setting the pattern for furth expansion over the next decade. There are indicatio of particular problems such as the proper relatic between the arts and the sciences, to which mo thought will clearly have to be given by the arts si as well as by the scientists. Alasdair MacIntyr writing on the modern universities and the Englis tradition, suggests that the inadequacy of the pr vincial universities arises from the lack of any cle conception of what the significance or purpose university life is. This ultimately derives from tl loss of the moral tradition which guided Englis provincial life for many decades and in which tl provincial universities were founded.

But it is not simply to the need for more con- uctive but fundamental thinking about the purpose university life that this symposium points. ually, as Mr. Kettle observes, we need an overall ucational perspective in the school and university stems of Britain. Far more important than con- rn with the alleged decline in academic standards the attack on the vast problem of improving e educational system as a whole, and Mr. Kettle inks that university people would be wise to use ore of their influence in trying to further that tack.

That is the only way in which Britain can deploy the best advantage the limited resources in man- wer, finance, equipment and building which it can vote to education. Unless those resources are anned as a whole, particular shortages like that science teachers will continue to exert an effect t of all proportion to their real magnitude and to fy any speedy adjustment except at high cost. rticularly should the expansion of technical and chnological education be planned in relation to one other, as well as in relation to the need for trained an-power and in relation to university education a whole, and to the conditions and needs of condary education in the grammar schools, the chnical schools and the modern schools.

This, however, is the weakest spot in the Govern- ent's proposals. Thus far the Government has nsistently refused to approach the question as a hole, and has persisted in dealing with each problem ecemeal and in isolation. This is the burden of r. John Wellens's paper on technical education and e shortage of scientists, technologists and tech- cians (see *Nature*, May 26, p. 967). He insists that e have not even yet the knowledge on which to tisfy ourselves that even the measures so far pro- sed are likely to be effective, and in particular he iticizes the White Paper for evading the re- xamination of the place of the technical school in e educational system of the country. Moreover, ke Sir Francis Simon and others, including Mr. . K. Brown, in his presidential address on May 20 the Association of Teachers in Technical Institu- ons, he urges the importance of establishing a body ke the University Grants Committee, competent not erely to ascertain the facts but also to secure the ncerted policy and action that the national interest mands, and too authoritative and informed to erlook dangers attending the scheme of the ational Council for Technological Awards for a ploma of technology.

Whether the Parliamentary and Scientific Com- ittee or any other body will be able to put effective essure on the Government remains to be seen; it the promised debate on the White Paper on chnical education offers an opportunity which ould be used to the full to explain what is involved a national policy and the points on which further formation is required as a matter of urgency. Mr. ellens's paper provides one good starting-point; ut there are many others. Moreover, while the niversities are formulating their own plans for the xpansion of their technological departments, Prof. J. L. Montrose's presidential address on May 25 to the Association of University Teachers shows that university teachers themselves are alive to the qualities required to ensure that technology or any other subject is carried out at a university-level, and that some fresh thinking is already proceeding both as to the purpose of a university and the functions of a department of technology and the content of its studies. Likewise, the trend of the discussions at the Conference of the Universities of Great Britain and Northern Ireland last December, both on the passage from the school sixth form to the university and on the age-group bulge and its possible effects on university policy, indicates that, in the universities and also in the schools, an attempt is being made to think out a common policy and to consider it against the educational needs of Britain as a whole rather than the interests or traditions of particular universities or schools.

The widespread debate that is thus already proceeding should help to form a public opinion alive to what is involved, and prepared to make the sacrifices that a concerted educational policy on the necessary scale will demand. There must, however, be no relaxation of effort on the part of professional associations of technologists, university teachers and of educationists generally to make sure that those issues are clearly understood, and that defects in the Government's proposals are firmly indicated and explained without ambiguity. But above all there must be an increasing disposition not merely to look at university and technological and technical education as part of a national educational policy, but rather to subordinate sectional and local interests to national needs.

ESSAYS ON SCIENCE

What is Science?

Edited by James R. Newman. Pp. viii+493. (New York: Simon and Schuster, Inc., 1955.) 4.95 dollars.

THIS is a symposium of twelve chapters each specially written for the book. The editor, already known as the co-author of "Mathematics and the Imagination" and other works, has done his work well and writes engagingly about his intentions. His claims concerning the book are honest, have been fulfilled and are worth quoting: "Though written for persons without special training, the pieces in this book are not always easy. Neither is modern science. A decent respect for the reader requires that he be told when a subject admits of no further simplification; the contributors have not pretended to explain what cannot be explained. Nevertheless, every effort has been made to speak plainly, to refrain from jargon and nebulous profundities, to enlighten rather than astound. Although some areas are too difficult for any deep explorations, the nature of the problem, the aims of its investigations and the instruments they use have been made clear". If some of the book is not easy reading, any expenditure of effort on the part of the reader will be rewarding: the issues have not been avoided in an over-facile attempt to popularize science in terms of exciting superficialities.

The book is published in the United States; but more than half of the authors are British. The sections are as follows: science and human life (Bertrand Russell); mathematics and logic (the late Sir Edmund Whittaker); astronomy and cosmology (Hermann Bondi); physics (Edward V. Condon); chemistry (John Read); biochemistry (Ernest Baldwin); biology (the late Warner Clyde Allee); evolution and genetics (Julian Huxley); psychology (Edwin G. Boring); anthropology (Clyde Kluckholn); psychoanalysis (Erich Fromm); and science as foresight (Jacob Bronowski).

Bertrand Russell sets the stage for the subsequent contributors in his essay on the social relations of science. "It is to progress in the human sciences that we must look to undo the evils which have resulted from a knowledge of the physical world hastily and superficially acquired by populations unconscious of the changes in themselves that the new knowledge has made imperative. The road to a happier world than any known in the past lies open before us if atavistic destructive passions can be kept in leash while the necessary adaptations are made."

The late Sir Edmund Whittaker follows with a chapter on the nature of mathematics from the philosophical and logical point of view. This is timely and useful in view of the fact that so much mathematics is devoted to the niceties of internal arrangement.

Prof. Bondi discourses on the modern cosmologies and deals with the internal constitutions of the stars in terms of terrestrial physics. This is followed by an account of the problems of modern physics, with special reference to fundamental particles and waves, by Dr. Condon. Prof. Read's treatment of chemistry is historical, and he is followed by Prof. Baldwin, who surveys the field of modern biochemistry with special reference to human physiology.

The late Warner Clyde Allee has a short chapter on the nature of a living matter, as a prelude to an understanding of the human organism; and Dr. Huxley gives a short historical account of a century's work in evolution and genetics considered in the light of present-day human problems. "Through the new knowledge, the evolutionary process was able for the first time to become conscious of itself. The next decisive step in evolution will accordingly be the fuller development of that self-consciousness. In particular, it will be the conscious clarification of the future in the light of the long evolutionary past and of the study of human potentialities. Once this has been done, greater realization of possibilities rather than higher productivity; fulfilment rather than efficiency will become the over-riding aim."

The chapters on psychology, psychoanalysis and anthropology contain historical accounts of their subjects from the practical point of view, and show their significance in relation to modern needs.

Of particular interest is Dr. Bronowski's last chapter of fifty pages on "Science as Foresight". "Machines, like animals, have evolved in two directions: the one toward muscle and strength, and the other toward brain and foresight. We can use knowledge to help us control our relations to our environment because it gives us foresight. That is, experience encourages us to believe that the future follows the past in a repeatable pattern; and knowledge helps us to isolate and to forecast this pattern." Thus, Dr. Bronowski deals with the new electronic calculators and follows with a simple description of those which have a mechanism for adaptation a learning. Such machines, which change not o their answers but also their approach to a probl as a result of their own findings, form an interesti analogue to the human brain. Dr. Bronowski de in a lucid manner, by using analogues and diagra with the circuits of electronic calculating machin binary notation and the programming of machin From here he touches on topics in the fields cybernetics, the exploring machine, game-playi machines, information theory, information a entropy. The last part of the chapter is devoted the logic of science and the nature of scient knowledge. He anticipates the development of machine which will have a more subtle, hum characteristic—that of being able to base foresig on insight. "The processes of nature can be pictur as messages written in a code whose unit-symb are unknown to us. All that we can do, at any st of our factual knowledge, is to prefer that code whi makes what we know most orderly. That is, choose those concepts which organize the messag of nature most coherently, by maximizing th content of information or meaning. This is the t for the inductions by which we try to generalize fr our particular experience and to gain a basis foresight."

There is an up-to-date bibliography with notes each book, given under the headings of the chapte

W. L. SUMNER

VIRTUOUS QUARRELS

Custom and Conflict in Africa

By Prof. Max Gluckman. Pp. ix+173. (Oxfor Basil Blackwell, 1955.) 12*s*. 6*d*.

THIS book contains the text of six lectures Prof. Max Gluckman that were broadcast the B.B.C. during the spring of 1955. Ea lecture is concerned with one of the standard topi habitually discussed by academic social anthrop logists, namely, feud, chieftainship, family structu witchcraft, ritual and race relations. The present tion is admirably clear. As a handbook for unde graduate anthropologists alarmed at the prospect approaching examinations, it can be heartily recor mended.

For the more sophisticated the interest of the boo is of a different kind. All six lectures are hooked a common theme which, in parody, might be repr sented thus: (*a*) people who quarrel are people wl have common interests; (*b*) people who live togeth as members of the same political corporation ha many common interests; (*c*) therefore, people wl live together as members of the same politic corporation will have many quarrels. Thus state the syllogism is no more than a logically fallacio platitude, and yet it is essentially the same as tl Durkheimian thesis that groups which express soci solidarity at one level of opposition will be internal segmented by faction at another. Prof. Gluckma has given the argument a novel twist by turning tl third leg of the syllogism back to front so as to read (*c*) therefore, people will have many quarrels in ord that they may live together as members of the sam political corporation.

Thus garbled, the argument might seem eve sillier than before, and yet in Prof. Gluckman's hand it becomes a most illuminating paradox. He show

r example, that the conventions which governed
e operation of the Anglo-Saxon vengeance group
ere rules which must lead to peace rather than
archic war. Similarly, he demonstrates that in
any different African societies there is a wide range
situations in which the hatred generated by
ructures of authority is quite explicit. Rebellion
gainst legitimate office-holders is almost institu-
onalized. Paradoxical perhaps, and yet clearly the
blic expression of hatred is also a public assertion
f the high value of that which is hated. The Barotse,
e are told, "state explicitly that it is the lot of
aders to be hated, because they are the Law itself".

With regard to the family, Prof. Gluckman argues
at, where relationship is effectively maintained
mong a wide circle of kinsmen, then husband and
ife must of necessity be somewhat estranged. Even
alice is claimed to have a positive value; witch-
aft accusations, by projecting the responsibility for
vil on to the scapegoat witch, permit the ordinary
an to retain his faith in the moral virtue of brotherly
ve even when his own daily actions are anything
ut kindly.

In all these cases there is the common theme that
is an essential feature of the working of any social
ystem that the 'friends' of one context should be
e 'enemies' of another. It is the divided loyalties
f the individual resulting from this contradiction
hich makes peaceful co-operation humanly possible.
his, it is maintained, is true even in the context of
e colour bar of South African native reserves. It
all very ingenious; such an analysis has many
pplications much nearer home than South Africa.
useful and well-selected reading list has been
dded to the text of the original spoken lectures.

E. R. LEACH

ICTIONARY OF TELEVISION AND RADAR TERMS

lsevier's Dictionary of Television, Radar and Antennas in Six Languages

nglish/American; French; Spanish; Italian;
utch and German. Compiled and arranged on an
nglish Alphabetical Base by W. E. Clason. Pp.
ii+760. (Amsterdam: Elsevier Publishing Com-
ny; London: Cleaver-Hume Press, Ltd., 1955.)
0s.

THIS is a most welcome addition to the reference
books dealing with the recent applications of
dio to radar and television techniques. Most
orkers in these fields find that, sooner or later, they
ave to discuss progress with their contemporaries
other countries or to read accounts of scientific
d technical progress in other languages. The
dvances made during the past decade have been so
volutionary that most existing technical dic-
onaries are in many respects obsolete. Moreover,
science becomes more and more international;
ere is a growing need for multilingual dictionaries.
was with the view of meeting this need that the
blishers planned a series of polyglot technical
ctionaries, of which this one is the first, dealing
ith television and radar and the aerials used with
th these applications. In planning this dictionary,
e author and publisher have been guided by certain
inciples proposed by Unesco. The object of these
inciples is to ensure that each dictionary produced
cording to them shall fit into place in a pattern which, it is hoped, may progressively extend over all inter-related fields of science and technology and cover all necessary languages.

The arrangement and lay-out of this volume have clearly been the subject of much serious thought and experiment. At each double-page opening the reader is presented with, on one side, the English term or phrase in bold-face type, and a brief but adequate definition of this term; while on the other page are given the equivalent terms in each of five other languages—French, Spanish, Italian, Dutch and German—the gender of the term being indicated in each case. Each definition is numbered at the extreme left and right, respectively, of the double page. The basic language being English/American (according to the publishers), these definitions are arranged in alphabetical order. But the book is completed by five alphabetical indexes for the other languages mentioned, giving the numerical reference to the English term. Where the usage of the 'English' term differs in Britain and in the United States, this is made quite clear, and the appropriate cross-indexing is included. It is interesting to note that a number of the terms are followed by the italic letters *sl*, meaning slang or code-names, which are or have been in common use among those engaged in the development and application of radar in Great Britain and the United States. Some, but not all, of these have been found to have equivalent terms in other languages.

The bibliography appended to the volume shows that full use has been made of the glossaries and technical dictionaries published in various countries, including those of the British Standards Institution, the American Standards Association and the International Civil Aviation Organization.

The publication of this work is very opportune at the present time in view of the growing importance of the exploitation of radio aids to aerial and marine navigation, and the need to facilitate the international exchange of programmes in the further advance of television. The production of the book is excellent; it is of a handy size, in a semi-flexible binding, and provided with a convenient thumb-index to the different languages. It should be readily available for immediate reference by every scientist and engineer engaged in the fields of television, radar and the associated antenna systems.

R. L. SMITH-ROSE

SPECTROSCOPY AT CENTIMETRE WAVE-LENGTHS

Microwave Spectroscopy

By Prof. C. H. Townes and A. L. Schawlow. (International Series in Pure and Applied Physics.) Pp. xviii+698. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 90*s*. 6*d*.

Spectroscopy at Radio and Microwave Frequencies

By Dr. D. J. E. Ingram. Pp. xii+332. (London: Butterworths Scientific Publications, 1955.) 45*s*.

MICROWAVE spectroscopy may in some respects be regarded simply as an extension of both radio-frequency measurements and of infra-red spectroscopy to the spectral region lying between 3×10^9 c./s. and 3×10^{11} c./s. (that is, to wave-lengths between 10 cm. and 1 mm.). The techniques of measurement may be derived from each of these limits or be entirely characteristic of the centimetre wave-length range itself. Thus the bolometer is more usually recognized as a detector for infra-red radiation, whereas the barrier layer rectifier is a circuit element often used at radio frequencies. Both of these may be used for micro-wave measurements; but in addition there are the reflexion klystron and magnetron as sources of power, the waveguides and cavity resonators as transmission networks which are features peculiar to the microwave techniques and warrant a separate discussion.

The results obtained from the microwave measurements also have some similarity to those derived from the radio-frequency and infra-red regions of the spectrum, but yet have additional and important contributions to present. Gaseous spectra in the infra-red are usually concerned with transitions between the molecular vibrational energy-states, and the rotational motion gives rise to a fine structure while nuclear effects are rarely resolved. In the centimetre region, however, the absorption spectra arise directly from rotational transitions, and a structure from the electric quadrupole moment of the nucleus is readily observed. The Stark effect also now gives rise to large perturbations of the energy-states and provides not only a useful method for detecting the spectra and identifying the transitions, but also enables the molecular electric dipole moment to be determined accurately. The Zeeman effect is less frequently used for the investigation of gaseous spectra, since few molecules are paramagnetic in the ground-state; but the extension of microwave spectroscopy to the absorption spectra from the solid state has been confined almost entirely to the investigation of transitions between the ground-state energy-levels of paramagnetic sites in crystal lattices. These measurements have provided detailed information about the ground-state wave functions of transition-group ions, they have allowed the determination of a number of nuclear spins, and they are powerful techniques for the investigation of the different types of chemical bonding and the structure of lattice defects.

The first measurements at centimetre wave-lengths were carried out in 1934 by Cleeton and Williams; but there was little subsequent work in this field of research until 1946, by which time the development of radar had provided sufficient instruments and experienced operators. During the past ten years, however, there has been such enormous activity that a review of the principles, the techniques and the results is now both desirable and necessary. To discuss adequately the whole field of microwave spectroscopy would be a formidable task, and the title of the book by Prof. C. H. Townes and Dr. A. L. Schawlow disguises the fact that these authors have very wisely limited themselves to a considered treatment of the microwave measurements on gases. It is a well-written book which treats the subject-matter with authority and maintains the reader's interest. The early chapters give a thorough discussion of the theory of microwave molecular spectra, while the later sections are concerned with the various microwave spectroscopes and contain a great deal of useful information about the measuring techniques. There is also an extensive bibliography with about a thousand references.

The book by Dr. D. J. E. Ingram is of quite a different type. The author has endeavoured not only to cover the whole field of microwave spectroscopy in all its aspects but also to include the radio-frequency measurements on molecular beams ar nuclear resonance. The treatment of individu topics is therefore necessarily very brief, and th reader may soon lose interest. One is left with t impression that too much has been concentrat within the compass of one volume, an impressi which is furthered both by the print and the diagram which also seem to be compressed. However, D Ingram's book does include a great deal of inform tion, and the reader seeking a more detailed discussi of any particular topic will find a carefully present series of references. It is a book, therefore, which a survey rather than an authoritative text and ma be found useful by many of those who are wonderi whether and how to start out into the field of micr wave spectroscopy.

D. M. S. BAGGULEY

POLYNESIAN TALES IN POETRY

Voices on the Wind

Polynesian Myths and Chants. By Kathari Luomala. Pp. iv+191. (Honolulu: Bernice Bishop Museum, 1955.) n.p.

ALL peoples have their folk-lore and fairy tale often transmitted in the form of poetry. The study is of great importance since past events as we as the outlook on life of the people themselv become enshrined in the tales. The story of Jas and the Golden Fleece probably results from a actual prospecting expedition to the head of th Black Sea. We can be very grateful, then, t Katharine Luomala for this volume, which recites number of Polynesian tales. A Maori mother tel her mischievous son that he is a "Maui-of-a-thousan tricks". The lad is flattered, since what boy in th South Pacific can ever hope to match a single pran of the demi-god, the hero of innumerable adventure But who was 'Maui'?

The Fakahina Island (formerly Niuhi) folk live an atoll around which blow violent winds tending force canoes out to sea. Here is a poem about it b some unknown Fakahina composer:

> This is Niuhi, land of gales.
> Sail the canoe outside—it is driven to sea.
> Sail the canoe inside—it is driven to sea.
> Mark, will you, the form of the land of Niuhi,
> Like a roll of Hala leaves,
> When sinks,
> When wanes,
> The Northeast wind.
> (Fails my breath!)
> O speed the fame of Niuhi
> to the world!

The account of the occupation of New Zealand too long to quote here, but is equally fascinatin Naturally, some of the tales owe their origin t outside influences—often impossible nowadays t trace. Thus the story of the hero who builds a gre boat just before a vast flood must have been intr duced into the folklore. Few people have grown u in entire isolation; somehow or other, ideas develope in one area found their way around the world eve in ancient times. But it is only when we hav studies like those under review that we can obtain picture of the ideas of a people and sometimes hin of past events in their history. The poems ar charmingly rendered into English and the blac and-white illustrations are delightful.

M. C. BURKITT

Electricity : Direct and Alternating Current

By Prof. Charles S. Siskind. Second edition. Pp. xii + 538. (London : McGraw-Hill Publishing Company, Ltd., 1955.) 43*s*.

THIS is an elementary text-book. As the author states in his preface, it "is intended for use in technical institutes, junior colleges, and short courses for non-electrical engineering students in universities . . ."

The first four chapters deal with direct current. Chapter 1 is concerned with basic ideas of conduction and the effects of electric current ; the second and third chapters deal with resistance calculations for conductors, and d.c. circuits, respectively ; the following chapter discusses basic theorems and laws, for example, those of Kirchhoff, and the superposition and maximum power transfer theorems. These are illustrated in terms of direct current ; but there is no mention of their application to the a.c. circuits, which appear in Chapter 5. As magnetism and electromagnetism are deferred until Chapter 6, this means that inductance is introduced before electromagnetism is touched upon. Then, unlike most British text-books, the chapter on electromagnetism has no mention of inductance. The remaining four chapters deal with d.c. measuring instruments, electromagnetic induction, generators, and motors.

The book on the whole is written quite clearly and is excellently produced. It would be suitable for National Certificate students. The advantage, however, of having such an American book (good of its kind as it is) in Britain does seem doubtful. The case against it is that it is expensive, there are British text-books available which cover the same material, and, of more consequence, the illustrations of usage and the units are those employed in American practice. As an example, flux density is quoted in kilolines per square inch, a quantity not commonly employed in British teaching.

W. FRASER

Chemistry of Carbon Compounds

A Modern Comprehensive Treatise. Edited by Dr. E. H. Rodd. Vol. 3, Part A : Aromatic Compounds. Pp. xxiv + 685. (Amsterdam : Elsevier Publishing Company ; London : Cleaver-Hume Press, Ltd., 1954.) 115*s*.

WITH the appearance of the first part of the third volume, this well-known compendium reaches that solid bed-rock of organic chemistry—the aromatic compounds. Although this is, of course, a well-trodden subject, recent work—for example, on 'benzyne' and the non-benzenoid aromatic compounds —shows that the field is by no means spent.

The volume begins with a series of articles by authorities which seek to survey the familiar facts in terms of modern concepts. Prof. C. K. Ingold contributes two such essays dealing with the benzene nucleus and orientation in electrophilic aromatic substitution ; the result is an object lesson in clarity and brevity. Prof. D. H. Hey and Dr. G. H. Williams perform the same function for nucleophilic and homolytic substitution, and Dr. N. Campbell ends this preliminary survey with a discussion of the formation and fission of the benzene nucleus.

The rest of the volume is devoted to a factual survey of the benzene series and simple derivatives thereof. This considerable task has been largely handled by Dr. W. J. Hickinbottom, with smaller contributions from Drs. J. Chatt and Z. E. Jolles. The presentation follows the pattern laid down in the previous volumes, although the enormous amount of material available has needed more drastic selection. More complex mononuclear derivatives and polycyclic and pseudo-aromatic structures are to be dealt with in Vol. 3, Part *B*.

R. A. RAPHAEL

Organic Chemistry

By Dr. I. L. Finar. Second edition. Pp. xv + 732. (London : Longmans, Green and Co., Ltd., 1954.) 40*s*. net.

THIS text, which is suitable for students reading for a university honours degree, was first published in 1951. It rapidly became popular, and a new edition was soon required. This popularity was possibly largely due to the author's plan of not adding the electronic theory as a tail-piece, but blending it in with the descriptive material, a plan which helps the student to make classifications and see inter-relationships and one that is conducive to an understanding of the subject. Conforming to the international rules of nomenclature, adopted in Britain by the Chemical Society in 1950, Dr. I. L. Finar has now written prefixes denoting substituents in alphabetical order. The new system was announced too late for inclusion in the first edition.

Among the other changes are enlarged sections on molecular orbitals, reaction mechanisms, stereochemistry, heterocyclic compounds and dye-stuffs. Thus the introductory section on molecular orbitals now occupies six pages. Dr. Finar, dispensing with mathematics, offers a simplified explanation of the concept and expounds its significance for the understanding of bonding problems. Thereafter, for instructional purposes, he uses it in conjunction with the valency-bond theory. These additions undoubtedly improve what was already a good book.

G. F.

The Moon

A Complete Description of the Surface of the Moon, containing the 300-inch Wilkins Lunar Map. By Dr. H. Percy Wilkins and Patrick Moore. Pp. 388 + 14 plates. (London : Faber and Faber, Ltd., 1955.) 63*s*. net.

THIS discussion of the physical features of the Moon's surface includes a chart in twenty-five sections on a scale of 32 inches to the Moon's diameter. It is reduced from the larger one by Dr. H. P. Wilkins published in 1952. Each section is accompanied by a description of the principal formations represented therein, the rectangular co-ordinates, elevations, and dimensions being given in most cases. The chart is based on visual and photographic observations, and the surface is shown in great detail. A number of large-scale drawings and reproductions of some excellent photographs supplement the chart. Considerable attention is given in special maps to features near the limb, which are difficult to study even under favourable conditions of libration and illumination.

The introduction summarizes the history of selenography and reviews the classification of the various types of formations. Several pages are devoted to an examination of suspected changes in the lunar surface that have been reported from time to time. A useful account of the techniques employed in lunar photography is given in an appendix by E. A. Whitaker.

The volume will provide for beginners an attractive introduction to the study of the Moon's surface ; for practised workers in the field it will serve as a useful supplement to earlier publications.

PEACEFUL USES OF ATOMIC ENERGY

By Dr. T. E. ALLIBONE, F.R.S.

THE papers submitted to the Geneva Conference last August were prepared at great speed, printed in many cases by offset lithography, and were illustrated with diagrams of indifferent quality. The United Nations is now publishing the full proceedings in a series of sixteen volumes in which the papers are grouped into main subjects, together with the discussion at the end of each session of the Conference. Vol. 3, on "Power Reactors", was the first to appear, followed by Vol. 2 on "Research Reactors" and Vol. 14 on "Isotopes"*. The volumes are printed on a high-quality paper on which all diagrams and photographs appear with excellent definition, and editing has been of such a high standard that in the detailed reading and study of a dozen of the papers I have failed to find a mistake. The discussion is recorded verbatim—which I think is a pity. In Britain we accept severe pruning of the printed record of a discussion in the interests of brevity; the recorded discussion in these columns could have been cut by 75 per cent without any loss of scientific context. However, the time allowed at Geneva for discussion was so short that it was the least important feature of the Conference.

Vol. 3, "Power Reactors", is for the engineer and applied physicist possibly the most interesting and important of all the proceedings. Here we have American, Russian and British accounts of the post-war design and construction of power reactors, and to many attending the Conference these accounts contained much that was new. There are also important authoritative plans for the future particularly emanating from the United States, while ideas from Holland contain great originality. To those who ask which country is ahead in reactor development, the answer can be given that all three of the Great Powers have 'firsts' to their credit: the American breeder reactor first produced 100 kW. of electrical power in 1951, and the submarine reactor produced an undisclosed amount of power in 1953; the Russian graphite water-cooled enriched reactor first produced 5,000 kW. of power in 1954; while the British 'first' will be the first 50,000 kW. generation of power from a natural uranium gas-cooled reactor—possibly this summer. In magnitude of effort based on population, Britain and America are almost on a par: Great Britain has two major developments, the gas-cooled natural uranium reactor and the plutonium breeder reactor, whereas America has her famous five-point programme of designs now being built. The U.S.S.R., on the other hand, would appear to be behind—at least plans were only referred to in very general terms, from which it is not possible to infer how many different types have been seriously pressed. In spite of the taunts often flung at the United States for its over-developed sense of security, the American papers disclose far more detail than the British or Russian papers, and in the Exhibition at Geneva there were beautiful examples of American fuel elements of all kinds.

As Dr. A. M. Weinberg stated in an opening review, there are a large number of types of reactor, of which a dozen or so are very promising; and the centra issue is to trace out of this welter those most likely to succeed. Again, it depends on what is meant by 'succeed'. Great Britain, with a limited gaseous diffusion plant, has chosen to concentrate on the design which uses natural uranium, whereas the U.S.S.R. prefers to build a 100,000-kW. station using a reactor enriched to 2·5 per cent; and when Academician Kurchatov was in Britain recently he stated that it is more economic to use enriched fue in a water-cooled reactor than to use natural uranium in a gas-cooled reactor. The United States five-point plan of reactors uses enriched fuel in all designs. The answer will not be found until the reactors have been built and operated for some years, during which time industry will be developing better designs of the existing types.

The American industrial reactor most advanced in construction is the pressurized water reactor (*P.W.R.*) being built by Westinghouse at Shippingport to supply 60,000 kW. of power to the Duquesne Light Co. and due to operate next year. Light water at 2,000 lb. per sq. in. is both the moderator and the coolant flowing through the reactor at 200 tons a minute and being raised only 34 deg. F. The pressure is kept high to prevent boiling, since boiling and steam formation result in instability of power output, localized hot-spots, and in pitting of the reactor vessel. (It is noted that in another American design boiling is freely allowed, and discussion did not clear up this paradox.) The reactor vessel is of formidable proportions, 33 ft. in height, 9 ft. in internal diameter and $8\frac{1}{2}$-in. wall thickness with a removable closure head. The core is small, only 6 ft. in diameter and height; it contains 12 tons of uranium in the form of oxide with an additional enrichment of $\frac{1}{2}$ per cent of uranium-235 localized in 'seeds' in the core, and will have a breeding coefficient of 0·8, that is, produce eight atoms of plutonium for ten atoms of uranium-235 undergoing fission. The design appears to be conservative and safe: the manufacture of pressure vessels is reliable, absence of boiling avoids many uncertainties, the temperature is moderate—only 540° F.—and the materials are well known; the only 'exotic' material is hafnium, used as a control rod. What is not easy is the detection and removal of burst fuel elements.

By contrast, the Argonne Laboratory has experimented widely with a water-cooled, water-moderated reactor operating at only a few hundred lb. per sq. in., so that boiling occurs low down in the core as the water is pumped upwards, and such a reactor to develop 5,000 kW. of electricity is now under construction. The daring experiments conducted on the first experimental reactor have shown how inherently safe is this design when steam voids are formed in the core, and when pressures are suddenly lowered or raised; no other reactor has been treated in this same free-and-easy fashion. Protagonists of this design also place weight on the lower temperature the fuel elements, with consequent less corrosion mage; but as there is such a big difference in wer output of the pressurized and boiling-water actors, the cost comparison given in the sum- rizing paper in this volume is not significant.

---

* Proceedings of the International Conference on the Peaceful Uses of Atomic Energy, held in Geneva, 8 August–20 August, 1955. Vol. 2: Physics: Research Reactors. Pp. viii+471. 8 dollars; 57*s*; 34 Swiss francs. Vol. 3: Power Reactors. Pp. viii+389. 7.50 dollars; 54*s*., 32 Swiss francs. Vol. 14: General Aspects of the Use of Radioactive Isotopes; Dosimetry. Pp. viii+305. 6.50 dollars; 45*s*., 28 Swiss francs. (New York: United Nations; London: H.M. Stationery Office, 1955 and 1956.)

The American sodium-cooled graphite-moderated actor is one of the most daring designs, and is due operate this year at a heat output of 20,000 kW. ot to be connected to an electrical generating ant). The attraction is the avoidance of high essures, the ability to reach high temperatures ,000–1,200° F. are mentioned in two papers, one which is speculative) and the ease—because of sence of a pressure vessel—of replacing fuel ments. The penalty is the necessity to encase the aphite moderator blocks in thin-sheet zirconium ns, and to conquer the problems of sodium or dium–potassium cooling; these had to be resolved r the fast-fission reactors and appear to be spoken with great confidence. North American Aviation . has a plan for a 75,000-kW. generating station sed on the present work, and anticipated costs are w.

One cannot, however, escape from the feeling that ere is a tremendous waste of metallurgical effort in actors so far described. All this advanced metal- rgy has to be undertaken so long as the fuel is sed in solid form; does the homogeneous reactor the liquid-metal fuel reactor point the way to the ture? The former is on the five-point programme, e latter has not yet got so far. The former has a ng history dating back to the Los Alamos 1944 ater-boiler; now it looks forward to producing ,000 kW. of heat this year using highly enriched anyl sulphate solution in heavy water, with a anket of thorium solution in which the breeding efficient may exceed unity. The design calls for ry high pressures—2,000 lb. per sq. in.—to prevent ullition; but the vessel for this power rating is ly 5 ft. in diameter, including the blanket. Another traction is the inherently high stability due to the gative temperature coefficient of reactivity; but ere are serious hazards, the greatest of which is akage, since the whole vessel and all the pipes to eat interchangers, etc., contain solutions carrying ssion products. This reactor does not appear to ve the support of industry; it is the work of the akridge Laboratory of the United States Atomic nergy Commission.

American industry has become much interested in e fast breeder reactor based to a large extent on e Argonne reactor now under construction for ,000 kW. of heat. In this, liquid sodium flows at 1,000 gal./min. past stainless steel tubes containing the core a plutonium–uranium alloy, and in the lanket uranium-238. In spite of the very high specific thermal loading, the reactor is regarded as safe, partly due to the large volume of sodium in the primary system which provides thermal inertia, and great hopes are centred on this engineering development: it holds out the ultimate goal of breeding all the fuel needed for future reactors; indeed, breeding *must* be successful for the long-term success of nuclear power.

The British reactor plans have received wide publicity, but the amount of detail supplied about the Dounreay reactor is far smaller than that for the Argonne reactor; so the reader of these volumes of the Geneva Conference is not able to judge whether the problems are being tackled on very different lines. The note of caution was struck more in the Dounreay description, and for safety the reactor is to be housed in a steel sphere, as is the American *G.E.* reactor; but the Argonne reactor is not so encased.

Vol. 2, "Physics: Research Reactors", supplies the basic information on which the power reactors have been developed, and describes the many forms of research reactors with which reactor experimentation has been and will continue to be done, including the testing of fuel elements in high neutron fluxes.

One-half of Vol. 14 is concerned with the preparation and use of radioactive isotopes in industry in many countries, the other half contains thirty papers on dosimetry. As Dr. P. C. Aebersold says in his opening review paper, "The Importance of Isotopes in Industry", the uses of isotopes have grown rapidly in nine years, but they are still far from attaining their world-wide potential for the gaining of new knowledge. The papers in this volume should be widely read by scientists in industry and in research associations, so that in appreciating what has been done readers may the more vividly appreciate what steps they can take in their own organizations. The diversity of uses is too great to review in a short paragraph; each country has some new examples to quote, but Mr. S. E. Eaton's American paper shows how a company specializing in tracer techniques can range far and wide in suggesting solutions to countless industrial problems of considerable complexity.

With the advent of kilocurie gamma-ray sources, the X-ray supply industry is affected. There is a big jump in the number of firms now using radiography for inspection and fault detection. We are about to enter a new phase of development, when megacuries of cæsium per annum become available from the power reactor processing plants, and when spent fuel elements may be employed to give doses of megarontgens per minute. With sources of these magnitudes, the chemical, agricultural and the food industries may begin to benefit on a really large scale in a few years time.

ECOLOGY OF *ANOPHELES GAMBIAE* GILES

By JAMES G. HALCROW

DURING the past three years, a small research unit of the Colonial Insecticides, Fungicides ad Herbicides Committee has been engaged in an ological study of *Anopheles gambiae* Giles in Mauritius. This insect has survived and increased; et as a result of an intensive house-spraying campaign, the incidence of malaria on the island has een reduced to very small proportions. It was considered desirable that the matter should be investigated.

Many workers in Africa have commented upon the ease with which this anopheline can transmit malaria; yet at no time has a *prima facie* case been made out against it as a vector of malaria in Mauritius. It has always been condemned on African, rather than local, evidence; though a worker in Mauritius, some thirty years ago, declared it was not "a domestic mosquito". The large-scale malaria eradication scheme of 1948–52 for Mauritius, based on residual insecticidal house-spraying, was, unfortunately, not fully documented on its entomological aspects ; but it did eradicate *Anopheles funestus* Giles, while failing to control *A. gambiae*. Malaria is almost unknown in the island, at the time of writing. The problem in 1952 was then a virtual absence of proved malaria in the abundant presence of a potentially powerful vector. Possible theories at that time were based on 'zoophilic' or 'DDT resistant' vectors. I have not obtained confirmation of them at any time ; I found *A. gambiae* to be a facultative feeder and to be generally highly susceptible to effective DDT contact.

The host preferences of *A. gambiae* were in 1952 quite unknown, though the high percentage with thoracic, and proboscal, infections of *Filaria bancrofti* argued against a purely zoophilic feeding regime. Stomach smears of 1,254 insects in all were examined at the Lister Institute, London ; most of them showed blood of bovine origin, but a majority of the insects were found in and around cowsheds. The majority of them preferred to rest in cowsheds, typical counts averaging 20–200 *gambiae* per cowshed. In houses examined, on the other hand, the average was less than one per hundred houses. It is further of interest that malaria and bancroftian filariasis are sometimes confined to the inhabitants of a small group of houses in a village. This 'parochialism' of *gambiae* may be due to the fact that it is not generally an insect of strong and sustained flight, so that little migration from an attractive feeding and resting site takes place. Captive female *A. gambiae* seem better able to mature their ovaries on a diet of human blood (see Table 1).

Table 1. Percentage of female *A. gambiae* maturing ovaries after a single feed of blood

Cow	62
Deer	49

In Mauritius, there is a wild-animal reservoir estimated at about ten thousand deer, plus many monkeys and some wild pig. In the sister island of Réunion, the wild animals are absent, and the people may therefore lack a valuable protective barrier against *A. gambiae*.

Figures were obtained which show that the nocturnal population of *A. gambiae* in cowsheds was largely composed of unfed mosquitoes. The day population of females was principally in the late blood-fed or half-gravid stages. Ovarian dissection of both day and night populations showed a ratio of nulliparous to parous insects of approximately 9 : 1. Gravid females were commoner in cowsheds by day than by night ; this suggests an early evening exodus.

By experiment in the insectary, the gonotrophic cycles (the time-interval between partaking of the initial blood meal and the commencement of egg-laying) were studied in the winter and summer seasons. The abdominal/ovarian classification used was that put forward by many authors, namely :

Stage 1.	Unfed :	thin, non-distended abdomen.
Stage 2.	Blood-fed :	abdomen gorged with fresh red blood.
Stage 3.	Half-gravid :	black mass of blood in abdomen ; apex of abdomen becoming yellow-white in colour.
Stage 4.	Gravid :	blood digested, abdomen distended with eggs.

The gonotrophic cycle in winter extended over 97 hr. ; that in summer took 94 hr. to complete. There did appear to be a tendency for the gonotroph cycle to shorten or lengthen according to the hos animal in use.

Activity cycles of *A. gambiae* were studied throug out the night on numerous occasions. (The nocturn study of a nocturnal insect is still so rare as to worthy of note.) It was found that the Mauritia *gambiae* reached its peak of activity earlier in t night than did the *gambiae* of Africa. At first, was not clear whether this might be due to som genetical difference, for an introduction of the mos quito into Mauritius would not, unless it were massed or repeated introduction, carry the fu genetical potentialities of the species. Howeve other Mauritian mosquitoes, for example, *Anophel constani* Lav., and *Culex fatigans* Wd., show th same early peak of nocturnal activity. From oth islands also there have come reports of *gambi* activity reaching a late crepuscular peak. It possible that the rapidly rising relative humidity the night air, in a small island, may cause the cessatio of flight activity.

After field-studies, the nocturnal activity *gambiae* was considered in the insectary, whe 'biting cycles' were studied. The 'biting cycle' w defined as the hour-to-hour fluctuation in a nocturn population of unfed *gambiae*, whether parous nulliparous female, which were seeking a blood-mea The 'activity cycle' was defined as the hour-to-ho fluctuation of a nocturnal population of *gambia* The latter cycle considers the population in genera the former judges the intensity of attack by t female on the host. The 'biting cycle' was foun to be some 1–2 hr. later in its peak than the gener activity cycle. The early nocturnal peak of activit of *gambiae* is of interest in that it coincides with t time of night when the human population are ou of-doors engaged in various and varied social activitie In effect, *A. gambiae* need never enter a house t secure a blood-meal. On the subject of houses, it noteworthy that the walls, treated annually wit DDT, are re-plastered with mud and dung ever New Year and on certain other festivals. A wa sprayed with insecticide two or three days previous may then be covered with fresh plaster and remai untreated until the next spraying.

It was confirmed that *A. gambiae* in Mauritius w a minor vector of bancroftian filariasis ; the maj vector was found to be *Culex fatigans* Wd., a mo quito not easily deviated from man ; indeed, it w noted that 84·0 per cent of the *C. fatigans* collecte from cowsheds had fed, not on cattle, but on ma The status of *A. gambiae* as a vector of malaria far from clear. Past records, when available, indica little of value. Of 4,526 dissections of stomachs an salivary glands since 1952, only two light stoma infections were observed. In the continued ar abundant presence of *A. gambiae* and the prese low level of diagnosed and proved cases of malari it would seem reasonable to regard *A. gambiae* as poor vector of malaria in Mauritius. It is no perhaps, remarkable that despite DDT and ant malarial drugs, malarial cases still occur from ti to time ; what is remarkable is that in spite of adult cides, larvicides, drainage works, and health educ tion, *gambiae* has not only survived but has eve increased its range. Its ability to recover fro natural catastrophes was seen in 1955, when torrenti rains and high winds caused by a close approach a cyclone destroyed the immature stages. Withi days, more immature stages began to appear, presu ably from eggs laid by the gravid females which sheltered indoors and had escaped destruction.

The rapid completion of the life-cycle during the summer months—about seven days from eclosion to adult emergence—undoubtedly helps the insects to make good any losses suffered. The winter life-cycle occupies about fifteen days from eclosion to adult emergence. Various authors have commented that, in Mauritius, the extinct *A. funestus* had a life-cycle at least three times as long as that of *A. gambiae*. It is possible that *A. funestus* was unable to build up its numbers when attacked by residual insecticides because its life-cycle is too long.

The ecology of the egg of *A. gambiae* was confined to eclosion studies, size of egg batches, and resistance shown by the eggs to salinity and desiccation. The duration of the egg stage in waters of known composition was found to be significantly longer in winter than in summer. Egg batches per female were larger in summer, both for the eggs of later gonotrophic cycles as well as for the first cycle. The numbers of eggs per batch fluctuated according to the host animal in use (Table 2).

Table 2

Host animal	Eggs per female *A. gambiae*
Man	140 ± 5·4
Deer	123 ± 8·9
Cow	111 ± 9·4
Guinea pig	105 ± 8·9
Rabbit	100 ± 9·6

Eclosion took place to some extent in water heavily charged with sodium chloride or copper sulphate. Continued development of the emerging larvæ was found to cease when the sodium chloride content rose to 17·5 gm. per litre. Eggs kept on damp filter-paper at room temperatures gave good eclosion-rates after 10–14 days. Normal eclosion was considered to be 78 per cent or more. Eggs placed on dry filter-paper at room temperatures failed to hatch after six days.

Standing agricultural water was found to form at least 43 per cent of all breeding sites. The sites of standing water in cane fields were ever changing; rarely did a site allow for the emergence of more than two generations. As one site drained away, or evaporated, another might appear as little as twelve inches away.

The period when the pupation-rate reached its maximum was studied by observing personally the pupation of 9,785 fourth instar larvæ (see Table 3):

Table 3

Time	Pupation (per cent)
Daylight hours (6.0 a.m.–5.0 p.m.)	12
Twilight ,, (5.0 p.m.–7.0 p.m.)	56
Night ,, (7.0 p.m.–6.0 a.m.)	32

Some little work was done on the parasites and predators of the larvæ of *A. gambiae*. Protozoan and fungal diseases were observed; but few results of any practical value were gathered concerning the predators.

Brief morphological studies were made; for example, (*a*) a study of the tarsal sensillæ, and (*b*) the maxillary index. Of (*a*) little resulted; clear-cut differences of taxonomic value were not to be found between individuals of the main population and individuals of the salt-water group. A comparative study of the maxillary dentitional range of *A. gambiae* and four other Mauritian mosquitoes has been made. The maxillary dentitional range of the Mauritian *A. gambiae* was determined to be twelve to sixteen teeth.

A subsidiary study was carried out on the saline-loving group of *A. gambiae*; known loosely (and wrongly) in Mauritius as either '*A. melas*' or 'salt-water *gambiae*'. In a paper to be published elsewhere, morphological and biological observations will be presented to support the erection of this group to formal sub-specific rank.

The full report on which this brief account is based has been deposited with the Colonial Products Laboratory, Imperial Institute Buildings, London, S.W.7.

THE ABYSSAL FAUNA: ITS ECOLOGY, DISTRIBUTION AND ORIGIN*

By Dr. ANTON FR. BRUUN
The *Galathea* Expedition, 1950–52, Copenhagen

Ecology

BEFORE defining the environment of the abyssal fauna, its relations to the other ecological zones of the deep sea must first be outlined. This is done schematically in Fig. 1, showing the percentage partition in area of the deep-sea floor, with respect to the intervals of depth against the profile. Light and temperature conditions as they apply to tropical and subtropical regions are also indicated.

Fig. 1 shows clearly the small volume of the water masses above the thermocline, centred at about 10° C., in comparison with the cold-water masses below the 10° C. isotherm. The comparison becomes even more striking when it is remembered that on the poleward side of the subtropical areas such cold water is found from the surface to the bottom. But even the water layers of 4–10° C. and the area of the bottom they occupy are relatively small in comparison with the huge body of water with temperatures always below 4° C. and covering the greater part of the deep-sea floor at depths of 2,000 m. or more. These are the true abyssal depths, the typical habitat of the abyssal fauna.

We must here disregard such highly interesting Seas as the Mediterranean, the Sulu and the North Polar, which have no connexion with the oceans at 2,000 m. and have therefore very different temperature conditions in their abyssal reaches. Also, their total area is very limited compared with that of the oceans.

Area. The total area of the oceans and seas adjacent to them is 361×10^6 sq. km. If the upper limit of the abyssal depths is set at about 2,000 m., their area is about 84 per cent of the total area. Even if the depths between 2,000 m. and

---

* Substance of three University of London lectures delivered at Birkbeck College on March 5, 7 and 9.

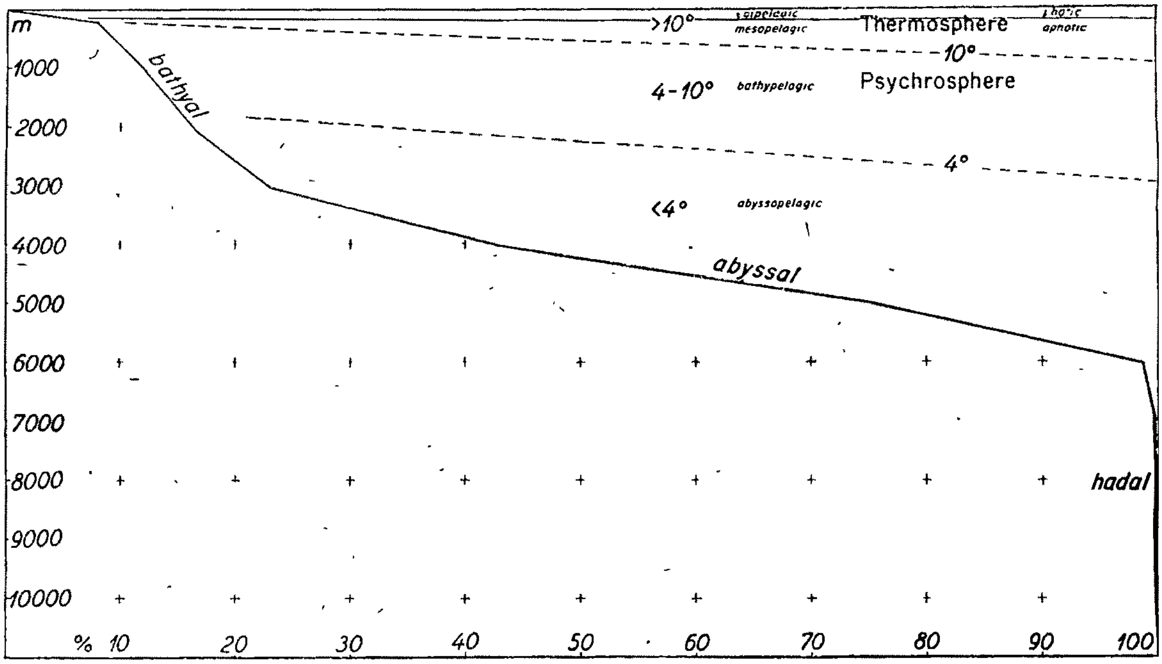

Fig. 1. Ecological zonation of the ocean

3,000 m. are excluded, the total area is only reduced by 6·8 per cent. If the extreme depths beyond 6,000 m. are excluded, there is further reduction of a mere 1·2 per cent. Therefore, by far the greater part, 273×10^6 sq. km. or three-quarters of the area, lies between 3,000 m. and 6,000 m. This is more than half the total area of the Earth (510×10^6 sq. km.). The abyss is thus the largest known ecological unit, but, unfortunately, also the least explored.

Sediments. The bottom is mostly covered by soft ooze or clay. Siliceous oozes occupy 38×10^6 sq. km., calcareous oozes 128×10^6 sq. km., and red clay 102×10^6 sq. km.

Temperatures. The abyssal zone is delimited from the bathyal zone by the temperature isotherm of about 4° C. This means that there will be a very narrow total range in abyssal temperatures, and a still narrower range within geographical areas. Furthermore, there is no seasonal variation in temperature.

Salinity. An average figure may be set at 34·8 per mille, and the variation is only about ± 0·2 per mille.

Oxygen. In general, the bottom water contains sufficient oxygen to support at least some life, as shown by the fact that large azoic areas are unknown. Koczy[1] has demonstrated a certain, sudden decrease of oxygen in the water layers from about 20 to 50 m. above the bottom down to a layer 1 m. above the bottom. In the Indian Ocean, this decrease amounts to values about 10 per cent of the oxygen content of about 4 ml./l. Brouardel and Fage[2] have shown a further decrease of oxygen in the last metre above the bottom at a depth of 460 m.

Alkalinity, pH; *carbon dioxide, phosphate and silicate.* Koczy has also shown a definite gradient of these chemical features close to the bottom, the alkalinity showing a slight increase, while the other constituents decrease. This phenomenon must be closely connected with biological processes; but more observations are badly needed.

Pressure. The ecological factors mentioned abov are not specific for the abyssal zone in the same sens as the hydrostatic pressure, which amounts to value from about 200 to about 1,100 atmospheres. Lac of light and low temperatures may occur at shallowe depths, but in combination with a high hydrostati pressure are only found in abyssal depths. This wa stressed by Fontaine[3], who carried out a series o experiments showing varying resistance to pressur in different animal groups; he also showed tha the rate of metabolism of *Pleuronectes, Gobius* an *Palaemon* increased with pressure. Others hav followed with similar experiments; but in all thes only shallow-water animals have been used. It wa not until ZoBell[4] succeeded in cultivating bacteri from the bottom of the Philippine Trench that th existence of organisms adapted to pressure wa proved. Such barophilic bacteria must be cultivate under a hydrostatic pressure of about 1,000 atmo spheres, and at a low temperature, because they ar also psychrophil and very steriothermal.

It is reasonable to conclude that more highl organized animals may be still more sensitive t pressure.

Food. All organisms living below the photo synthetic zone must depend upon the amount o food existing in or sinking below this zone. The ol idea of a rain of dead bodies of plankton organism reaching the deep-sea floor, has not been sub stantiated by finding such a settling in any quantity But if *food* is thought of in terms of *any energ stored in organic matter,* there is certainly a rain o excrement, cast crustacean skins, tests of salps, etc. which, however, cannot be digested directly b animals. Nevertheless, 30–40 per cent of the remain ing organic carbon can be converted into bacteria cell substance, the rest being oxidized by the bacteri during the process. Such bacteria may serve directl as food, with protozoans, mud-eaters or filter-feede as the second link in a new food-chain.

It is commonly asserted that the greater the dept the less the supply of food. This is probably not so because the abysso-pelagic zone is so poorly populated, even with bacteria, that the amount of organic debris reaching the bottom is much the same whether the depth be 2,000 m. or 10,000 m. provided the supply from the surface is the same. Even any bacterial decomposition during the sinking must be inhibited, because of the steadily increasing pressure, and only at the bottom itself can bacterial activity really start.

It is well known that a certain number of abyssal animals live close to the surface as larval stages, such as the leptocephali of the deep-sea eel *Synaphobranchus*. When such larvæ metamorphose and start living at the bottom, they must provide a considerable amount of directly available food for the abyssal predators. Only a small fraction of the number which descend ultimately grow up for recruitment to the breeding stock.

Other direct sources could be the dead bodies of surface animals which are too big to be swallowed by any predator. Ear bones of whales and the teeth of sharks—the more permanent remains of these animals—are often found on the abyssal floor. A dead whale of 50 tons must attract scavengers for a long time and thus form a local focus of abundant food for predators.

There are several sources of indirectly available supplies; but their relative importance is difficult to estimate.

The amount of dissolved organic matter is probably very important. It is certainly fairly high, about 0·5 mgm./l., according to the few determinations made first by Krogh[5] and more recently by Plunkett and Rakestraw[6]. But more determinations are needed from water very close to the bottom in order to estimate the rate at which organic matter is consumed by bacteria.

Besides the particulate organic matter of animal origin already mentioned, remains of land plants, such as branches, leaves or fruits, together with seaweeds from the coastal belt, have often been included in hauls from deep water (Fig. 2). Except for a very limited amount, all this debris must be converted by bacteria into digestible matter for animals.

In many regions where plant debris has been found to be abundant, the quantity of animals has been correspondingly great.

On the whole, the food supply in the abyssal zone may not be termed plentiful; but it is no more scanty than in any other benthic zone of the deep ocean below the layers in the proximity of the photosynthetic zone.

Animal communities. It is not possible to give even an estimate of the number of species of the abyssal zone, since new species still appear in almost every haul. Furthermore, the taxonomy of several groups needs a thorough revision, which will again reduce the number of species described. It is therefore of very limited interest to state, for example, that eighty-eight species of the holothurian order Elasipoda have been found in depths exceeding 3,000 m.; or, similarly, that the ophiuroid family Ophiolepididae is represented by forty-nine species.

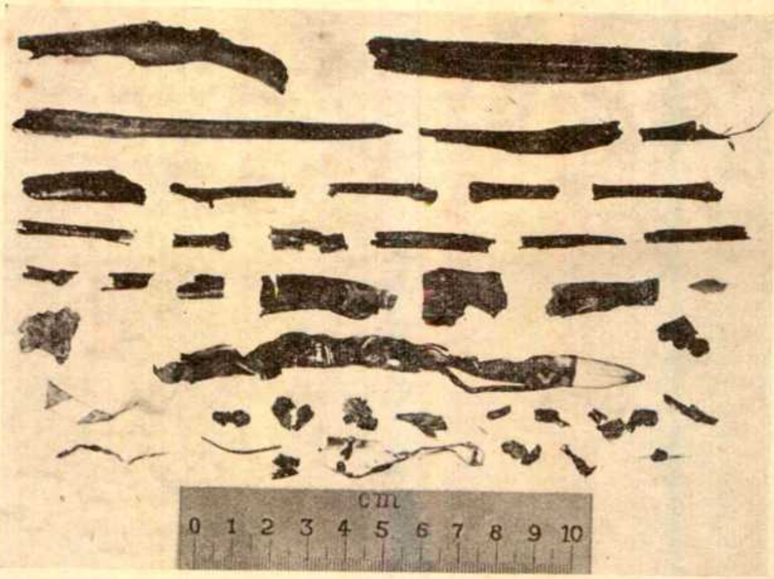

Fig. 2. Plant debris from the bottom of the Philippine Trench, 10,190 m.

Nevertheless, the figures must in some way indicate quite a varied fauna, and the same impression is apparent in several other major taxons.

However, the abyssal fauna can scarcely be compared with the diverse communities of a coral reef. This is not surprising, because most of the environmental conditions in the abyssal zone are so extremely uniform. The food supply and the increasing pressure with depth are the exceptions.

Ecologically, the fauna forms a typical soft-bottom community with a dominance of burrowing species, mixed with sedentary stalked species, like sponges, cœlenterates and tunicates. Exposed rock surfaces, which are relatively rare, have been even less explored than the level bottom and have revealed a poor epifauna. This is so because the quiet conditions allow sedimentation to take place on much steeper slopes than those of shallower water with its strong currents and wave action.

It appears impossible to single out any character of morphological adaptation, which is not also seen in animals from shallower ecological zones.

Distribution

Vertical. Many species have a very wide range, extending upwards even to the continental shelf; but there is no doubt that the number of species decreases steadily with increasing depth. Between 6,000 m. and 7,000 m. a considerable number of major groups disappear. This is the transition zone leading to the depths of the trenches, which at 10,000 m. in the Kurile Trench[7] and the Philippine Trench[8] contain only six and eight species, respectively. The Danish investigations in the shallower Sunda, Banda, New Britain and Kermadec Trenches gave similar results, and systematic studies have shown a large number of new species found nowhere else. Combined with ZoBell's work on barophilic bacteria, the impression is gained that the trenches form an ecological zone of their own, for which the term 'hadal' is suggested (*hades*, the Greek underworld). The all-important biological factor in the hadal zone is the high hydrostatic pressure, 600–1,100 atmospheres.

Even within the true abyssal zone, 2,000–6,000 m., there is a certain degree of segregation into an upper and a lower subzone. The fish *Acanthonus* has been found only in the upper division, whereas another fish, *Bathymicrops*, has been found only in the deeper. In addition, it may be stated that Russian and Danish investigations both found the lower limit of fish at 7,200 m., each of the expeditions finding one specimen at that depth.

Horizontal. If an animal is living at 2,000 m., there is no biological barrier between any of the oceans. Therefore, it would be expected that the true abyssal animals would be cosmopolitan, and so in general they probably are. Both the fishes *Acanthonus* and *Bathymicrops* are, and further examples appear in every systematic treatment of new collections.

But there are certain striking exceptions. One example is the interesting class of Pogonophora, which have been found only in the north-west Pacific and in the equatorial Indonesian Seas. A probable explanation of this distribution could be the great variation in the food supply, which is abundant in both the areas where the Pogonophora have been found. There may well be other similar instances. It seems likely that the food supply is the most important factor governing the horizontal distribution of the true abyssal species.

The hadal species could also be governed by pressure to the extent that if a species has become barophilic, it has no possibility of spreading from one trench to another, so that each trench will tend to contain a special endemic fauna. A fine example of this was found by the late O. Carlgren of a new family of Actinaria represented by one species in the Philippine Trench and another in the Kermadec Trench (an account is in the press).

Origin

The true abyssal fauna is derived from the bathyal fauna, from which such species that can live under the higher pressure and at lower temperatures have spread downwards. Exploration of the abyssal zone has thus added but little to the list of living fossils which it was expected would be discovered when the first stalked crinoids were found more than a century ago. But the majority of stalked crinoids are bathyal, and so are the hexactinellid sponges and the eryoneid crustaceans and the cœlacanth fish *Latimeria*. This bathyal distribution was clearly seen so long ago as 1899 by Perrier[9], when he suggested the name the Palæozoic zone for the depths from 400 m. to 2,000 m. because of the many similarities with the cretaceous fauna.

It seems probable, therefore, that the temperature in abyssal depths in Tertiary time and earlier, when there were no constant polar ice-caps, was between 4° and 10° as in the present bathyal zone. This agrees very well with the results of Emiliani and Edwards[10], who examined the oxygen isotopes of benthic Foraminifera of probably Oligocene age from the eastern central Pacific. They found temperatures around 10° C., where to-day it is about 2·5° C. So the relatively sudden onset of the glacial age and its cooling of oceanic deep water must have been catastrophic for the abyssal and hadal faunas. Only the relatively eurythermic and eurybathic species could survive.

The present composition of the hadal fauna may indicate the types of animals which survived; if taxons higher than subspecies are exclusively of hadal occurrence, they must be relics of a preglacial abyssal or hadal fauna. But besides these old components there must have been a new invasion, which started with the first glaciation and is presumably still going on. The lower part of the bathyal zone and even coastal waters of the polar regions have yielded species of the necessary eurybathic capacity.

The *Challenger* Expedition opened up the abyssal world eighty years ago; but hadal organisms have been known for less than ten years. Collections now being studied may soon lead to changes in some of the points of view given here; but very much more field-work must still be carried out before we have a knowledge of the abyssal and hadal zones which will stand comparison with that of coastal seas.

NEWS and VIEWS

Biochemistry in the London School of Hygiene and Tropical Medicine: Prof. H. Raistrick, F.R.S.

PROF. HAROLD RAISTRICK, who retires from the chair of biochemistry in the London School of Hygiene and Tropical Medicine at the end of the current session, graduated at Leeds in 1912. There he came under the influence of J. B. Cohen, to whose training in organic chemistry so many British biochemists are indebted. He was engaged for a brief period on research on the proteins of milk and then proceeded to Cambridge, where he worked in the laboratory of Sir Frederick Gowland Hopkins and first became interested in the metabolism of micro-organisms. He was the first grantee in microbiological chemistry of the Medical Research Committee, conducting government research on the production of acetone by fermentation. After receiving the degree of D.Sc. (Leeds) in 1920, he accepted an industrial post and for eight years guided the activities of the newly formed biochemical laboratory of Nobel's Explosives Co. at Ardeer Factory, Stevenston, Ayrshire (later merged into Imperial Chemical Industries, Ltd.). Here he initiated the pioneering work on the metabolic products of the micro-fungi which was to prove the main interest of his research career.

Returning to academic life, in 1929 Prof. Raistrick was appointed to the University chair of biochemistry in the London School of Hygiene and Tropical Medicine. He was then able to publish the investigations undertaken at Ardeer in a series of eighteen papers forming the first group of "Studies in the

Biochemistry of Micro-organisms". This work received very favourable comment; the Sc.D. (Cantab.) and the fellowship of the Royal Society soon followed. The major part of his research work during the tenure of his chair has been devoted to the continuation of the studies on micro-fungi, and the contributions in this main series of papers which has flowed from his laboratory now number nearly one hundred. Prof. Raistrick has served as secretary of the Biochemical Society and has devoted much time to administrative and advisory duties in the University of London. During the Second World War he was honorary scientific adviser on penicillin production to the Minister of Supply; in 1949 he was Bakerian Lecturer of the Royal Society.

Prof. J. H. Birkinshaw

Dr. John Howard Birkinshaw, who is already reader in biochemistry in the London School of Hygiene and Tropical Medicine, is to succeed Prof. Raistrick. Like Prof. Raistrick, Birkinshaw is a graduate of the University of Leeds, eventually gaining the degrees of M.Sc. and D.Sc. from that University. In the First World War he held a commission in the West Yorkshire Regiment, took part in the Somme offensive and was captured at Delville Wood, to be repatriated shortly after the Armistice in 1918. He commenced his research career as a research biochemist in the Ardeer Factory of the Nobel's Explosives Co. Here began his long association with Prof. Raistrick, whom he succeeded as chemist in charge of the Biochemical Department at Ardeer when Raistrick moved to the London School of Hygiene and Tropical Medicine. In 1931, the senior staff of the Biochemical Department at Ardeer moved to Prof. Raistrick's department in London, where Birkinshaw remained until 1937, when he went for a year to the I.C.I. Research Station at Jealott's Hill to work on the conservation of grass protein. In the following year, he was appointed senior lecturer in Raistrick's department at the London School of Hygiene and Tropical Medicine, becoming a reader in the University of London in 1945. Dr. Birkinshaw is a Fellow of the Royal Institute of Chemistry, and has been a secretary of the Biochemical Society. The greater part of his research has been devoted to the study of metabolic products of micro-fungi, a field which he and Prof. Raistrick have together developed with great distinction.

Psychology at Oxford: Prof. G. Humphrey

When Prof. George Humphrey retires from the chair of psychology in the University of Oxford next September, he will be able to look back over the past nine years with great satisfaction. He went to Oxford in 1947, after a distinguished career in the United States and Canada, returning as a professor to the University which he had first attended as an undergraduate. Anybody who visited the Institute of Experimental Psychology, in the Banbury Road, then, and who revisits it now, will speedily realize how great a development has taken place. It is fair to say that psychology at Oxford has made more advances during these years than at any earlier period, and in particular that excellent working relations have been established with other academic studies. All is now well in train for still more striking developments. It is remarkable that, with all this, Prof. Humphrey has also found the time to complete and publish those studies in the experimental psychology of thinking for which he has now become known throughout the world.

Prof. R. C. Oldfield

Prof. R. C. Oldfield, who is to succeed Prof. George Humphrey at Oxford, took his first training at Cambridge, reading the Natural Science Tripos, Part 1, and Moral Sciences Tripos, Part 2. He was an exhibitioner in moral sciences at Peterhouse and held the Arnold Gerstenberg studentship in philosophy, and the Leverhulme fellowship in industrial psychology. For a time he worked with Prof. Cairns in Oxford on head injuries, holding a Rockefeller research fellowship. During the Second World War he was with the Radar Branch of the R.A.F., being mentioned in dispatches. After a period of lecturing at Oxford, first in general then in experimental psychology, he was called to the chair at Reading in 1950. He was a founder-member of the Experimental Psychology Group and edited the *Quarterly Journal of Experimental Psychology* for some years, and still serves as associate editor. His interests in psychology have been unusually broad, extending from applied psychology (his monograph on the "Psychology of the Interview" is well known) to the effects of head injuries and the contrivance of a number of ingenious pieces of apparatus such as that for the continuous recording of sensory thresholds. In addition, he has published many experimental and theoretical papers covering a wide range of subjects. During his six years tenure of the chair, the department at Reading has steadily increased its reputation for progressive experimental work.

Mathematics at Glasgow: Prof. I. N. Sneddon

Prof. I. N. Sneddon, of the University College of North Staffordshire, has been appointed to the newly created Simson chair of mathematics in the University of Glasgow. Named after Robert Simson, who was professor of mathematics in Glasgow during 1711–61, the new chair has been set up in order to strengthen the link between the Mathematics Department and the Faculty of Engineering. The new professor will be responsible for the mathematics courses given to students of engineering and for the advancement and exposition of mathematical methods. The need for engineers skilled in mathematical techniques of various kinds has never been greater than at the present time, and there is great scope for the holder of such a chair to meet this need and develop his subject. It would be hard to find anyone better fitted to do this work than Prof. Sneddon. Appointed at the early age of thirty to the chair of mathematics at the University College of North Staffordshire, he has been responsible for the setting up and working out of new courses of mathematics there and has still found time to carry on his own research work and write several books, as well as doing valuable work on committees of the Scientific Advisory Council. He has an impressive range of mathematical techniques at his disposal which he has applied to a wide range of subjects in applied mathematics and theoretical physics. His main work has been on elasticity, and his recent work on the generation of waves in elastic solids by variable body forces is of particular interest.

Washington University, St. Louis, Mo.: Physics Appointments

Dr. E. U. Condon, visiting professor of physics at the University of Pennsylvania, has been appointed professor of physics and chairman of the Department of Physics of Washington University, St. Louis, Mo., in succession to Prof. George E. Pake, who has been appointed to the chair of physics at Stanford University. Dr. Condon was previously director of research and development of the Corning Glass Works during 1951–55, and before that was director of the National Bureau of Standards, Washington, D.C. In 1953 he was president of the American Association for the Advancement of Science. Two other appointments in the Department of Physics have also been made: Dr. M. W. Friedlander, of the University of Bristol, England, to be a research associate with the task of establishing a nuclear emulsion group for the study of high-energy nuclear processes; and E. B. D. Lambe, of Princeton University and the University of British Columbia, whose speciality is paramagnetic resonance, to be assistant professor of physics.

University of Durham

THE University of Durham has announced the following appointments: Dr. W. B. Fisher, reader in geography, to the professorship of geography in the Durham Division; Dr. P. L. Robinson, reader in inorganic chemistry, to a personal professorship of inorganic chemistry in the Newcastle Division; Dr. E. G. Richardson, reader in physics, to a personal professorship of acoustics in the Newcastle Division; Dr. J. Weiss, reader in the mechanism of chemical reactions, to a personal professorship of radiation chemistry in the Newcastle Division.

Falkland Islands Geological Work at Birmingham

A CONTRACT has been concluded between the Colonial Office and the University of Birmingham, as a result of which the geological work of the Falkland Islands Dependencies Scientific Bureau (the director of which is Sir Raymond Priestley) will for the next three years be done in the Department of Geology at Birmingham. The primary object of this arrangement is the production of a basic geological map and evaluation of the stratigraphy and economic resources of the Dependencies. Field work in the antarctic will continue as before, under the control of the Governor of the Falkland Islands. At Birmingham, the facilities of apparatus, comparison material and library will be made available to holders of newly established fellowships, some of whom will be appointed to deal with petrological and palæontological collections already made, while others will be men who have returned from a tour of field work and will require a further year or two years to work out their results. To co-ordinate this work, the University has appointed, under the title of Senior Research Fellow in the Department of Geology, Dr. R. J. Adie, who has, among other qualifications for this position, several years of practical experience in the Dependencies, and a number of publications on their geology.

Training B.B.C. Engineers

PRIOR to 1946, technical training within the British Broadcasting Corporation was carried on in a number of regional studio centres and at some of the large transmitting stations. It was then found necessary to centralize engineering training at Wood Norton Hall, near Evesham, in a special department, which has just passed its tenth anniversary. The head of this B.B.C. Engineering Training Department is Dr. K. R. Sturley, formerly assistant principal of Marconi College, Chelmsford. With the completion of some new buildings this year, about two hundred students can be accommodated on full-time residential courses of training, which cover both sound and television broadcasting. Every effort is made to avoid duplicating the training in electrical engineering given in universities and technical colleges; but the application of basic principles to the equipment and methods used by the B.B.C. is studied in detail. While radio engineering normally calls for a very high standard of mathematics and technical knowledge, a feature of the B.B.C. courses is the selection and presentation of special instruction in broadcasting engineering so that it can be readily understood by staff without advanced mathematical knowledge. This involves the use of special demonstration equipment, most of which is constructed in the department's laboratories and workshops.

The various courses cover such subjects as sound recording, acoustics, studio lighting, and transmitters and aerial design for various frequencies. The courses vary in length up to twelve weeks, terminating in examinations, and the successful candidates are then eligible for promotion. A series of booklets, entitled "Engineering Training Supplements", have been prepared by the staff, dealing with such subjects as the principles of television lighting, audio-frequency amplifiers and frequency modulation; and these are used to augment the lectures and demonstrations. In the past ten years, nearly four thousand men and women have passed through the Department; and during 1956 the number attending the various courses is expected to rise to more than eight hundred.

Industrial Trade Associations in Great Britain

IN a broadsheet issued last year (*Planning*, 21, No. 383; 1955), Political and Economic Planning presents a preliminary account of a new survey of manufacturers' trade associations which is being conducted in co-operation with industry. It excludes associations concerned solely with research or with labour or management and also general bodies which represent industry as a whole, and, in addition, it excludes associations consisting entirely of distributors. Besides an analysis of the services offered by associations to their members, the inquiry attempts to assess the effectiveness of trade associations' activities in representing members from the point of view of various bodies which have contacts with such associations, and it is also intended to approach many manufacturing firms to discover what trade associations mean to them in the course of their business. There appear now, in 1955, to be more than a thousand such associations in existence; of these, more than two hundred are concerned with the textile and clothing industries and more than a hundred with each of the following industries: chemicals and allied trades; metal manufacturers; metal goods; engineering and shipbuilding; and food, drink and tobacco. Two main types of general, broadly based associations covering many specific interests can be distinguished: the federation comprising local or product associations, such as the British Man-Made Fibres Federation and the Wool Textile Delegation; and the large industry-wide association which may or may not have local or product associations affiliated to it, of which the British Electrical and Allied Manufacturers Association is an example. The broadsheet lists some thirty-seven different activities undertaken by some or other associations and reviews briefly the three main aspects of their work: representation of the industry; provision of common services (including exchange of information and experience and publicity); and economic regulation. Of the first, the broadsheet notes, besides presentation of a united front to other organizations, including government departments, the value of trade associations as a source of expert advice; of the second, that much valuable work is done in the fields of safety and health; and of the third, that not more than 15–20 per cent are concerned in any way with prices.

Taxonomy and Origins of Cultivated Bananas

A FURTHER useful and interesting contribution to our knowledge of these topics has been made by N. W. Simmonds and K. Shepherd (*J. Linn. Soc.*, Botany, **55**, No. 359, 302; 1955). Two wild species, *Musa acuminata* Colla and *M. balbisiana* Colla, are considered to be the sources from which virtually all the edible bananas have originated. Earlier investigations had led to the view that there were edible diploid and triploid forms of *M. acuminata*, of diploid and triploid forms of interspecific hybrid origin, and of triploid forms of *M. balbisiana*. Simmonds and Shepherd now point out, however, that this view of banana taxonomy presents difficulties, in that no edible diploid forms of *M. balbisiana* are known, and that, although mechanisms for the production of vigorous tetraploid bananas are well known from cytogenetic experiments, only one such banana is known to occur naturally. They have now used a taxonomic scoring method for classifying the edible bananas and to provide evidence on their evolution. Edible diploid forms of *Musa acuminata* are thought to be the primary source of the whole group to which another species, *M. balbisiana*, has contributed by hybridization. Thus there exist diploid and triploid edible forms of *M. acuminata* and diploid, triploid and tetraploid hybrid types of genetic constitutions that vary according to their histories. There is a faint possibility that a third wild species has contributed to the origins of a small group of triploid hybrid types. Triploidy was probably established under human selection for vigour and fruit size; tetraploidy is inexplicably rare. The centre of origin of the group is Indo-Malaya, and Malaya is probably the primary centre. The two Linnæan species, *M. paradisiaca* and *M. sapientum*, refer to identifiable edible varieties which are both shown here to be of hybrid origin. The names, therefore, may be rejected from the nomenclature of the wild bananas.

Poultry Housing

POULTRY keeping in England and Wales has undergone great changes since the last edition of Bulletin No. 56 "Poultry Housing" was published by the Ministry of Agriculture and Fisheries in 1935. Interest in intensive and specialized methods has much increased, and the type of housing and equipment required has been altered accordingly. A complete revision of the Bulletin has now been carried out, keeping in mind the needs of those following both the older and newer methods. The approach to the subject is essentially practical, and the Bulletin, which is now in its fifth edition (pp. 56+4 plates. London: H.M.S.O., 1955; 2*s*. 6*d*. net), contains a large number of excellent diagrams and photographs. Before describing the principles of design and construction, useful advice is given on layout, choice of building materials and the accommodation requirements of different classes of birds. Stress is laid on the importance of good ventilation, lighting and protection from extremes of weather, and practical information given as to how these needs may best be met. The Bulletin should prove helpful to poultry keepers of all types in establishing an efficient unit at a minimum cost.

Scientific Film Review

AS a result of a change in publication policy by the Scientific Film Association, the *Scientific Film Review* has been issued in a new format. The change is intended to create a journal which not only contains more film reviews than were previously published annually but which also provides a means of informing members and subscribers of the activities of the Association and of developments in the production and application of scientific and industrial films. The new journal will appear every second month. Three issues each year will contain film reviews and appraisals, articles on various aspects of scientific and industrial films, and other information of interest to all concerned with the application of film to scientific and industrial problems. The other three issues will generally be devoted to films on specific subjects. The first special issue of this kind will be published in June and will be devoted to films on chemistry. The present issue (2, No. 1; April 1956) contains articles on the film and work study, first steps in industrial film making and the use and abuse of film in medical illustration. There is also a classified list of medical films which have been notified during the past two years.

Health Education in the U.S.S.R.

IN September 1955 a group of fifteen medical men went to the Soviet Union to study preventive medicine. They made a journey covering some eight thousand miles from Leningrad to Moscow, Tashkent, Samarkand, Sochi, Stalingrad, back to Moscow and finally to Leningrad. Their experiences have been recorded by Dr. John Burton (*Health Education*, 14, No. 1; March 1956). In the U.S.S.R., the doctor considers the purpose of medicine not to be the alleviation of suffering but the raising of the standard of living; prevention takes precedence over cure. The health services are not divided into cure and prevention, as they are in Great Britain, with hospitals and general practice on one side and public health on the other. Their divisions are pædiatrics, adult medicine and environmental sanitation. Prevention and cure in these fields are carried on simultaneously in the same building, namely, the polyclinic. Every health worker—nurse, physician, sanitarian or surgeon—studies health education during his or her training.

Decisions on Zoological Names for Certain Birds

THE International Commission on Zoological Nomenclature has recently taken a series of decisions on the names for certain birds regarding which applications to the Commission were published in October 1952 in Part 1/3, Vol. 9, of the *Bulletin of Zoological Nomenclature*. Among the decisions so taken, the following are of wide general interest: (1) suppression of the generic name *Colymbus* Linnæus, 1758, and acceptance of the generic name *Gavia* Forster, 1788, for the divers (loons) and of *Podiceps* Latham, 1787, for the grebes (Opinion 401); (2) validation of the generic name *Pyrrhocorax* [Tunstall], 1771, for the chough by the suppression of the name *Coracia* Brisson, 1760 (Opinion 404); (3) suppression of the specific name *ericetorum* Turton, 1807, and acceptance of the name *philomelos* Brehm, 1831, for the song thrush (Opinion 405); (4) suppression for nomenclatorial purposes of the names by Linnæus published in 1776 in the "Catalogue of Birds, Beasts, . . . in Edwards' Natural History" (Opinion 412); (5) validation of the name *Columba migratoria* Linnæus, 1766, for the passenger pigeon (Direction 18); (6) validation of the generic names *Bubo* Dumeril, 1806, *Coturnix* Bonnaterre, 1790, *Egretta* Forster, 1817, and *Oriolus* Linnæus, 1766, by the suppression of older homonyms (Direction 21); (7) acceptance of *Gallinago* Brisson, 1760, and rejection of *Capella* Frenzel, 1801, as the generic name for the snipe (Direction 39). These decisions are being published. All inquiries should be addressed to the Publications Officer, International Trust for Zoological Nomenclature, 41 Queen's Gate, London, S.W.7.

Northern Advisory Council for Further Education

The eighth annual report of the Northern Advisory Council for Further Education shows how one of these regional organizations is stimulating and canalizing the development of technical education in its area. Growing interest in fuel efficiency, for example, has been followed not only by the further education and training of boiler-house operatives but also by the provision of a refresher course in fuel technology for works and plant engineers at Middlesbrough. Suggestions by the Ministry of Education that local authorities could usefully develop their range of advanced courses has led to the organization of *ad hoc* courses in analytical chemistry at Whitehaven, work study at Darlington, Gateshead and Newcastle, and the testing of materials and the design of fabricated structures at Sunderland. Courses projected for the 1955–56 session include one on surges at Newcastle, transistors at Workington, lubrication at Middlesbrough, and metallic corrosion and protection at Sunderland. All the authorities within the region are considering the organization of courses for industrial personnel in communications and report writing. Copies of the report can be obtained from the Secretary, National Advisory Council for Further Education, 5 Grosvenor Villas, Grosvenor Road, Newcastle upon Tyne, 2.

National Science Foundation, Washington, D.C.: Fellowships for 1956–57

The National Science Foundation, Washington, D.C., has announced the award of 775 pre-doctoral graduate fellowships and 80 post-doctoral fellowships in the natural sciences and allied fields for the academic year 1956–57. Of the former, 296 fellowships have been awarded to first-year students, 302 to students in their intermediate years, and 177 to those in their last year. The distribution among subjects is as follows: chemistry, 182; physics, 165; engineering sciences, 109; mathematical sciences, 67; zoology, 58; earth sciences, 40; psychology, 26; biochemistry, 25; microbiology, 20; botany, 16; medical sciences, 14; agriculture, 11; anthropology, 11; genetics, 7; astronomy, 7; general biology, 3; and biophysics, 3. In addition, 11 awards have been made in fields where the natural sciences converge with the social sciences. Of the post-doctoral awards, 29 have been made in the life sciences, 19 in chemistry, 13 in the mathematical sciences, 9 in physics and astronomy, 5 in the earth sciences, and 2 in the engineering sciences. All the awards are tenable at any accredited non-profit educational institution of higher learning in the United States or abroad. The pre-doctoral fellowships are worth 1,400 dollars for the first year, rising to 1,800 dollars for those in their last year, and post-doctoral fellowships are worth 3,400 dollars. The fellowships include additional allowances for dependants, tuition and other normal expenses.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division, Colonial Office: G. W. Anderson (agricultural officer, Uganda), senior agricultural officer, Uganda; D. G. Jones (agricultural officer, Tanganyika), assistant director of agriculture, Tanganyika; D. K. Jones (agricultural officer, Cyprus), senior agricultural officer, Cyprus; R. B. Smith (agricultural officer, Trinidad), agronomist, Trinidad; R. B. Warner (senior agricultural officer, Western Region, Nigeria), principal agricultural officer, Western Region, Nigeria; C. C. Webster (chief research officer, Kenya), deputy director of agriculture, Federation of Malaya; J. D. Yelf (agricultural officer, Northern Rhodesia), senior agricultural officer, Fiji; W. V. Calder (assistant conservator of forests, Tanganyika), assistant conservator of forests, Uganda; W. H. Jack, J. W. C. Mooney, D. Sim, J. W. Wheelan and J. C. Wilson (assistant conservators of forests, Gold Coast), senior assistant conservators of forests, Gold Coast; H. A. Douglas, D. C. Duff and D. A. Lane (senior assistant conservators of forests, Gold Coast), conservators of forests, Gold Coast; D. Moore (assistant conservator of forests, Trinidad), deputy conservator of forests, Trinidad; P. C. Randell (senior assistant conservator of forests, Northern Region, Nigeria), conservator of forests, Northern Region, Nigeria; J. H. N. Smith (assistant conservator of forests), conservator of forests, Northern Rhodesia; A. E. G. Storrs (assistant conservator of forests, Gold Coast), assistant conservator of forests, Northern Rhodesia; I. G. Hughes (geologist, Gold Coast), senior geologist, Gold Coast; G. C. Billington (senior statistician, Gold Coast), deputy statistician, Gold Coast; J. M. Simmond (statistician, Gold Coast), senior statistician, Gold Coast; W. Stewart (senior pharmacist, Eastern Region, Nigeria), chief pharmacist, Eastern Region, Nigeria; A. E. H. Phillips, technical publications officer (agriculture), Federation of Nigeria; M. Dagg, scientific officer, East Africa High Commission; Miss S. J. Darke, medical research officer, grade III, East Africa High Commission; G. B. Aneuryn-Evans, statistician, Federation of Nigeria; P. Durran, veterinary officer, Northern Region, Nigeria; J. McP. Fletcher, assistant director of agriculture (veterinary and animal husbandry), British Guiana; A. D. Morris, veterinary officer, Western Region, Nigeria; D. A. Richardson, veterinary officer, Nyasaland.

Royal Society of South Africa: Officers

The following have been elected as officers and members of council for 1956 of the Royal Society of South Africa: *President*, S. H. Haughton; *Honorary General Secretary*, W. J. Talbot; *Honorary Treasurer*, N. Sapeika; *Joint Honorary Editors*, W. J. Copenhagen and A. M. Talbot; *Honorary Librarian*, E. Newbery; *Other Members of Council*, W. F. Barker, H. B. S. Cooke, J. H. Day, A. J. H. Goodwin, S. M. Naude, W. S. Rapson, S. H. Skaife and R. H. Stoy.

Royal Aeronautical Society: Officers

The following have been appointed officers for 1956–57 of the Royal Aeronautical Society: *President*,

E. T. Jones; *Past Presidents*, N. E. Rowe, Sir Sydney Camm and Sir William Farren; *President-elect*, G. R. Edwards; *Vice-Presidents*, Sir Arnold Hall, P. G. Masefield and Dr. E. S. Moult; *Honorary Treasurer*, Major G. P. Bulman; and *Secretary*, A. M. Ballantyne.

Rutherford Memorial Lecture and Scholarship

Under the terms of the scheme to commemorate the late Lord Rutherford of Nelson, the Council of the Royal Society has appointed Prof. E. N. da C. Andrade to deliver the Rutherford Memorial Lecture for 1957 in Australia.

The Council of the Royal Society has also appointed Mr. A. M. Segar, a graduate of the University of Melbourne, as a Rutherford Scholar for three years from October 1, to carry out studies in nuclear physics at the University of Birmingham.

Human Problems of Industrial Communities within the British Commonwealth

A study conference on "The Human Problems of Industrial Communities within the Commonwealth and Empire", under the presidency of H.R.H. the Duke of Edinburgh, and with Sir Harold Hartley as chairman, will be held in Oxford during July 9–27. The purpose of the conference is to conduct a practical study of the human aspects of industrialization, and in particular those factors which make for satisfaction, efficiency and understanding, both inside industrial organizations and in the everyday relations between industry and the community around it. It will not deal, however, with those matters which come within the normal scope of industrial negotiation. As the conference is independent in character, no government or organization is represented officially, and the members have all been invited as individuals and not delegates. About 280 men and women will be attending, mainly 25–45 years old, and all of them responsible persons engaged in the manager/employer or trade union/operative roles of industry (including industrially organized agriculture and government-owned undertakings). The approximate distribution of membership is: Great Britain, 90; Canada, 30; Australia, 25; India, 25; Union of South Africa, 18; Malaya and the Far East, 14; Caribbean area, 13; Federation of Rhodesia and Nyasaland, 12; Pakistan, 12; West Africa, 11; New Zealand, 10; East Africa, 7; Oceanic areas, 7; and Ceylon, 6. The conference will be divided into twenty study groups of fourteen members each, and after the introductory sessions they will set off for nine days on independent tours of industrial centres in Britain. The last five days of the conference will be spent in Oxford, when the final reports of each group will be discussed. Further information can be obtained from the conference secretary, Peter Parker, 48 Bryanston Square, London, W.1.

Announcements

The Warner Memorial Medal of the Textile Institute has been awarded to Dr. J. M. Preston, research manager of British Enka, Ltd., of Aintree. The Medal was inaugurated in 1930, in memory of the late Sir Frank Warner, a past president and chairman of Council of the Institute, and is awarded for outstanding work in textile science and technology, the results of which have been published, and particularly for work published in the *Journal of the Textile Institute*.

The Salters' Company has elected the following to be Salters' Fellows for the year 1956–57: F. W. Eastwood and R. C. Sheppard (Department of Organic Chemistry, Cambridge); Dr. L. Keay (Queen Mary College, London); and Dr. M. J. Stephen (continuation of fellowship for 1955–56; Department of Mathematics, Oxford). Salters' scholarships have been awarded to the following: A. R. Sanderson (King's College, Newcastle upon Tyne); P. S. Houston (Battersea Polytechnic, London); A. A. Webb and P. L. Levine (Imperial College of Science and Technology, London); and B. B. Hunt (University of Cambridge).

Sir K. S. Krishnan, director of the National Physical Laboratory of India, New Delhi, will give a lecture at the Royal Society on June 28 at 4.30 p.m. in which he will give a short account of the scientific and technical work done in the various divisions of the Laboratory. The lecture is open to the public, who should write beforehand, however, to the Assistant Secretary, Royal Society, Burlington House, London, W.1, notifying their intention to be present.

The Manchester Joint Research Council is holding a meeting on "Automation" in the University of Manchester on July 9. The meeting will be addressed by the Earl of Halsbury. Further information can be obtained from the Council, c/o Manchester Chamber of Commerce, Ship Canal House, King Street, Manchester 2.

The Nutrition Society is holding a symposium on "Grassland and the Feeding of Livestock" in the University of Reading on July 20, under the chairmanship of Prof. H. D. Kay. Further information can be obtained from the honorary programmes secretary of the Society, Dr. R. J. L. Allen, c/o Beecham Foods, Ltd., Brentford, Middlesex.

The Plant Breeders' Conference organized by the Agricultural Research Council will be held this year in the Plant Breeding Institute, Cambridge, during July 4–5. About a hundred representatives are expected to attend, including the staffs of plant breeding institutes, other plant breeders and geneticists from university departments.

A symposium on "Chemisorption", organized by the Chemical Society, will be held in the University College of North Staffordshire, Keele, during July 16–19. After an opening session on the theory of chemisorption, there will be four sessions dealing with chemisorption on insulators, metals, carbon and semiconductors, respectively. The fee for the symposium is 2 guineas (10*s*. for Fellows of the Society). Registration forms, to be returned by July 1, and further information can be obtained from the General Secretary, Chemical Society, Burlington House, London, W.1.

The Non-Destructive Testing Group of the Institute of Physics will hold its summer meeting during July 11–14 in the H. H. Wills Physical Laboratory, University of Bristol, when the subject will be "Physics of Some New Aspects of Non-Destructive Testing". The proceedings will be published later as a supplement of the *British Journal of Applied Physics*. The conference will be open to non-members of the Group. Enrolment forms, to be returned by June 25, can be obtained from the Deputy Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

THE GROWTH OF LEAVES

THE University of Nottingham held its third Easter school in agricultural science during April 23–25. It took the form of a discussion, with demonstrations, on leaf growth. Prof. F. G. Gregory (Imperial College, London) opened the symposium by outlining some general aspects of leaf growth. The initiation of leaf primordia poses certain questions, especially if a hormone theory is invoked, since two groups of cells arise from the same apex—one forms a leaf capable of only limited growth and the other the axillary bud with the potential of unlimited growth. Cessation of cell division restricts the growth of the leaf, the size of which is determined by the number of primordial cells, the rate and duration of division and the size of the mature cells. Analysis of the growth curves of leaves can assist in understanding the way in which various factors influence leaf development. Temperatures below the optimum, for example, mainly influence the rate of growth of the primordia. A photochemical reaction is involved in the production of specific leaf-forming substances; but the nature of the reactions involved in leaf growth is little understood. Prof. E. Bünning (University of Tübingen) pointed out that capacity for division and unlimited growth are common properties of protoplasm, but that these are restrained by polarity and the close proximity of meristematic areas. Meristemoids arise in areas sufficiently removed from other meristems, and these in turn tend to suppress this tendency to unlimited growth. The self-duplication of substances produced by developing cells is responsible for the stable organization and ordered differentiation of the plant. The changes which occur during the growth and differentiation of cells were described by Drs. J. K. Heyes and R. Brown (Agricultural Research Council Unit of Plant Cell Physiology, University of Oxford). Cell enlargement is not simply the expansion of a metabolic system of constant pattern but involves a system in which the pattern itself changes. Metabolic activity is low in meristematic cells due to a high proportion of protein with low catalytic activity. During expansion, the relative proportion of catalytically active protein as well as the total protein increases, and there are changes in the activity of different enzymes which determine the rate and course of growth.

The inception of leaf primordia in several different plants was described by Prof. C. W. Wardlaw (University of Manchester). The position of inception of the primordium and its symmetry, orientation and rate of growth are regulated by the activity of the apex as a whole and can be disturbed by surgical and chemical treatments. There is need for much closer study of the constitution and metabolism of cells in the different regions of the apex, since these determine the formation of growth centres and control the geometrical pattern of leaf arrangement. This arrangement, or phyllotaxis, was rigidly defined by Dr. F. J. Richards (Imperial College, London), who indicated alternative methods of estimating phyllotaxis height. An equation was also derived which has wide applications to growing and dividing systems generally. In one form it yields a relation between the cross-sectional area of an apex, the slope of the apical surface relative to the longitudinal axis, the primordial insertion area, the plastochrone, and the difference between two transverse growth-rates; it then consists of two parts, each of which represents the phyllotaxis height corresponding to the particular plastochrone considered. The metabolic changes in such a system were examined by Drs. N. Sunderland, J. K. Heyes and R. Brown (Agricultural Research Council Unit of Plant Cell Physiology, University of Oxford). Such changes may be regarded as a consequence of the primary differentiation from the apex of the tunica with low metabolic activity and the corpus with high activity. Cell division and protein accumulation are restricted in the corpus; but substrates are transferred from it to the tunica to supply materials for the rapid division and protein synthesis which occurs in this region of low inherent synthetic activity. A similar pattern occurs during development of the leaf primordium when metabolic activity increases from a low to a high level.

The changes which occur at different stages during expansion, producing a variety of different leaf forms, were outlined by Dr. H. Jones (University College, Aberystwyth). In juvenile leaves the primordial form persists to maturity; in other leaves, changes may occur at an early stage of development and may also be related to changes in width of the shoot apex. Changes in shape during expansion result from localized differences in divisions and growth; these may be analysed by using the allometric relation. Size and shape may be altered by various physical and chemical agents. From defoliation experiments with apple, Mr. H. W. B. Barlow and Mr. C. R. Hancock (East Malling Research Station) postulated that at least three different substances or groups of substances are produced by leaves and influence the growth of other leaves. One of these groups probably consists of the major photosynthetic products, a second is a factor (or factors) produced by immature leaves which influences internode extension, and the third a leaf-growth factor which influences cell division. The influence of length of day on leaf development was discussed by Prof. E. Bünning (University of Tübingen). Short days accelerate leaf production by long-day plants and retard it in short-day plants, but the rate of ageing of leaves of both types is hastened in long days. Although there is little difference in the total growth made during the light and the dark period, there are definite fluctuations in growth-rate during these periods, the maximum occurring at different times depending on the species. Prof. W. T. Williams (University of Southampton) discussed the association of light with leaf growth in terms of the etiolation phenomena of leaf suppression and internode extension which is exhibited in its absence. Suppression of etiolation by brief flashes of light is associated with the initiation of cell division; but the amount of division set in train is out of all proportion to the light stimulus given. It appears that the synthesis of leaf proteins is automatically initiated by a brief period of light; the process once started continues, irrespective of further light.

During the final session, the effect of external factors on leaf growth was discussed. Prof. F. L. Milthorpe (University of Nottingham) emphasized that most changes occur during the primordial stage. Although low temperature retards all processes, differentiation of primordia appears to continue at a higher rate than does the rate of division and expansion of cells leading to growth of a leaf. The stage of growth is also important; following a temperature check, a higher relative growth-rate of leaves occurs if some leaves have expanded than if no leaves are present. The influence of conditions at germination persists long into the growing period. Prof. G. E. Blackman (University of Oxford) discussed the effects of light and temperature on leaf growth. These vary with the species: reduction of light intensity below full spring and summer daylight may have little effect on the leaf area of one group of plants; in another group, there may be a large increase in leaf surface with reduced light almost to the compensation point; whereas in a third the effect may be intermediate. There is, in general, a direct curvilinear relation of net assimilation-rate and an inverse relation of the leaf area ratio with light intensity; the resultant effect on relative growth-rate, being the product of these terms, depends on the magnitudes of the responses involved in these two relations. The retarding effect of increasing light on leaf expansion occurs with intensities greater than 300–600 ft.-candles; at lower intensities there is a positive effect. Leaf area increases with temperature up to about 25° C., but interactions occur between different levels of temperature and light. Dr. H. L. Penman (Rothamsted Experimental Station) showed that the growth of grass is closely proportional to the total energy supplied at the surface, and also to the potential transpiration. Water becomes limiting at small values of soil moisture deficit; these values are smaller with low than with high nitrogen supply. The slope of the curve relating growth to incoming radiation is also influenced by the nitrogen-level. Dr. D. J. Watson (Rothamsted Experimental Station) emphasized the general conclusion that the variation in dry-weight yield per acre is determined mainly by leaf growth. Variations in the rate of photosynthesis have little influence. The maintenance of dense leaf coverage during the major portion of the growth period provides the main possibility of increasing yield. There is a limit, however, to the increase in returns possible, as mutual shading of leaves ultimately reduces the net assimilation-rate sufficiently to offset the gain from the larger leaf surface. Yield of grain depends largely on a large leaf area during grain formation.

The points raised in the papers were vigorously discussed, and some of the conclusions and techniques used were demonstrated. Full proceedings will be published elsewhere.

F. L. MILTHORPE

FRESHWATER BIOLOGY IN SCOTLAND

THE symposium during April 9–10 on freshwater biology in Scotland, arranged by the Institute of Biology (Scottish Branch), was the first occasion when a comprehensive survey of the progress of work on Scottish fresh waters has been presented. This being so, it is natural that it should cover a wide diversity of subjects. Subjects which ranged from the effects of hydroelectric schemes on migratory fish to the emergence of aquatic insects were submitted for discussion by speakers from the Universities of Edinburgh and Glasgow, the Brown Trout Research Laboratory, Pitlochry, the Oceanographic Laboratory, Leith, and the North of Scotland Hydro-electric Board. The topics brought forward for discussion in the first two sessions were not unrelated, and most can be fitted into a sequence commencing with conditions for life in Highland waters and passing to ecological aspects of the flora and fauna.

It was reported that streams of the catchment areas of Highland lakes and rivers are markedly subject to excessively rapid run-off, partly due to the removal of vegetation by clearing of timber and the burning of moors and partly also to extensive channel draining of sheep pastures. When peat is exposed it is not as efficient a water store as might be supposed. Rainfall reduces the surface layer to a colloidal gel, which inhibits deeper penetration and enhances rapid surface drainage into water-courses, which, in their upper reaches, usually flow down steep slopes. The result is extensive erosion in the lower reaches under storm conditions. Rapid drainage and influx of peat derivatives into Scottish lakes are contributory to the main cause, the mineralogical nature of the Highlands, of the paucity of plant nutrients in these waters. More than half those studied have a calcium content (expressed as $CaCO_3$) of less than 10 p.p.m. and nearly all have less than 50 p.p.m. They have not evolved to a degree of eutrophy permitting the reversible oxidation-reduction process described by Ohle[1] and Mortimer[2], with the result that plant nutrients tend to be occluded in the bottom muds and their main source lies in the small amounts brought in by inflowing streams.

Studies on phytoplankton in Scottish lakes, especially the application of Nygaard's[3] 'compound quotient' to a general survey, emphasize the oligotrophic nature of the majority. This quotient, which is the number of species characteristic of eutrophic waters (for example, species of Chlorococcales and Myxophyceae) divided by the number of species characteristic of oligotrophic waters (for example, species of Desmidaceae), displays a correlation with chemical evidence and with productivity of bottom fauna. Where past records exist, it has been possible to demonstrate the rate of evolution of a lake. Loch Leven, in Fife, with a quotient of 2, fifty years ago ranked as mesotrophic. To-day, with a quotient of 8, it is eutrophic. Loch Lomond, on the other hand, has shown no change over the same period.

Known in England only in the Lake District, the cladoceran crustacean, *Holopedium gibberum*, is absent from eutrophic waters but abundant in many oligotrophic lakes in Scotland. The conditions governing its distribution are not yet fully understood, for it is absent from some water bodies which appear to be closely similar to those in which it does occur. A possible clue to the uneven distribution is the presence of a certain minimum amount of dissolved organic material in the water.

The impermanence of fresh waters was discussed from another aspect, that of their invasion by pulmonate gastropods. It was suggested that the co-existence of pulmonates with a wide range of adaptations, from the great phenotypic plasticity and high ratio of selection—that is, number of individuals surviving to breed annually—of *Lymnaea peregra* to the great genotypic specialization and low ratio of selection of *Ancylus fluviatilis*, may be credited to the instability of freshwater habitats relative to their marine counterparts.

In papers on freshwater fishes and their parasites, during the second day of the meeting, interest lay in new or little-known occurrences in Scotland. Among endoparasites of fishes, the strigeid trematode, *Cotylurus erraticus*, was reported to form massive metacercarial infestations around the heart of powan, *Coregonus clupeoides*; with an incidence of 100 per cent in Loch Lomond, but apparently absent from these fish in Loch Eck, their only other habitat. Present also in trout from Lochs Lomond and Leven, *Cotylurus* does not attain in them the same high infestation. This difference in degree of infestation may be related to differing habits of the hosts, in that trout are fluviatile for at least their first year, whereas *Coregonus* spends its whole life in the lake.

The pseudophyllidean cestode, *Triaenophorus nodulosus*, occurs in pike in Loch Lomond, and its finding constitutes the second record for Britain. Since plerocercoids of this species have been found only in yearling pike, it would appear that the life-cycle is dependent on cannibalism. Apart from the consideration of their parasites, pike were shown to have a phase in development which is probably the retention of an archaic actinopterygian characteristic. The embryos hatch when the branchial region, pectoral fins and mouth are still imperfectly developed and, for a period of about ten days, hang suspended from water plants. They are attached to the support by the secretion of two cement glands placed in front of the eyes.

An addition to the Scottish fauna was established among the fishes. A biometrical study of char, *Salvelinus alpinus*, recently discovered in Loch Eck, Argyll, yielded results which give this fish the rank of a distinct sub-species.

CHEMISTRY OF OXYGENATED HETEROCYCLIC COMPOUNDS

INTERNATIONAL COLLOQUIUM AT LYONS

LESS than two months after the Dublin symposium on naturally occurring pyrones (see *Nature*, 176, 637; 1955), a similar meeting, devoted more particularly to naturally occurring flavonoid compounds, was held in Lyons during September 5–10. Twenty-six scientists from ten different countries took part in these discussions, during which the different aspects of the chemistry of oxygenated heterocyclics were reviewed.

The first series of reports were in the field of organic chemistry. M. Mousseron (Montpellier) discussed the reactions of epoxides in relation to their steric structure. He suggested a new method for their quantitative estimation in the presence of —SCN ions. The fixation of water by epoxy-1 : 2-*cyclo*alkanes was discussed. The epoxide structure occurs in the transition states of many reactions and leads to compounds having a *trans* configuration.

G. Sandris and G. Ourisson (Paris) discussed the synthesis and properties of 2 : 2 : 5 : 5-tetramethyltetrahydrofuran. Mention was made of the effect, on the spectral properties of this type of compound, of replacement of the heterocyclic oxygen by methylene. In some cases, for example, when there was an α-diketonic group in the 3- or 4-position, the authors achieved a molecular rearrangement to a four-membered ring (trimethylene oxide).

The chemistry of coumarins in general was reviewed by N. P. Buu-Hoï (Paris). The most reactive position in coumarone is the 2-position while in thionaphthene it is at the 3-carbon. A molecule like brasane is far less reactive than the analogous polycyclic hydrocarbon (naphthacene).

C. Mentzer (Lyons) gave an account of the synthetic methods leading to benzopyrone compounds (coumarins, chromones, flavones and their derivatives). The methods were classified according to linkages formed. The condensation of an aromatic C_6 group with C_3 molecules was discussed in detail. A complete list of coumarins, chromones and flavanones obtained by the author and his collaborators by the 'thermal condensation' of phenols with malonic or β-ketonic esters, was given.

A. Dreiding (Zurich) has synthesized 5:6:7:8-tetrahydrocoumarin by a Reformatsky reaction between ethyl monobromacetate and 2-(hydroxymethylene) *cyclo*hexanone. It may be possible to apply this method to the synthesis of other α-pyrones starting from β-dicarbonyl derivatives.

In a second series of papers, the oxygenated heterocyclics were discussed with emphasis on the biochemical aspects. As in the Dublin symposium, the flavones and their derivatives, as well as other less well-known lactones, were the focus of attention.

T. R. Seshadri (Delhi) showed the possibility of the *in vitro* transformation of flavanones into dihydroflavonols by the addition of an oxygen atom to the 3-position. This can be achieved : (*a*) by bromination or iodination of the acetyl derivative of the flavanone and subsequent treatment with silver acetate ; (*b*) by the action of lead tetra-acetate ; (*c*) by the action of Fenton's reagent (hydrogen peroxide + ferrous ion) on the acetyl derivatives.

T. S. Wheeler and E. M. Philbin (Dublin) discussed molecular rearrangements in the flavonoid field. The Wessely–Moser rearrangement has been extended to chromanols and dihydroxyxanthones. A new type of rearrangement was described in which the 2-aryl nucleus takes the place of the second benzene nucleus in the flavone molecule.

The chemistry of natural aurones was reviewed by T. A. Geissman (Los Angeles). These substances (benzal-2-coumaranones) occur in many higher plants of the genera *Cosmos*, *Coreopsis*, etc. The author, who recalled the work of Marini-Bettolo, Hattori and others, has studied their synthesis, properties, detection in plants, isolation and spectral properties in relation to structure.

S. Hattori and M. Shimokoriyma (Tokyo) presented two reports, one dealing with flavonic glycosides from the leaves of *Calystegia japonica* and *hederacea*, the other on the localization of the flavonoid pigments in '*Cosmos sulphureus*'. It is interesting to note that *Calystegia japonica* Choisy (Convolvulaceae) contains a rhamnoglucoside of kæmpferol, in which the disaccharide unit located in position 3 has been identified as rutinose, while *Calystegia hederacea*, a species so similar as to be easily mistaken for the former, contains kæmpferol 3-galactoside identical with trifolin from the flowers of *Trifolium repens*.

Dihydroflavonols were discussed by J. Gripenberg (Helsinki). These compounds are of interest because of the manner in which they become rearranged in alkaline media. In contrast to what happens in aurones, the rearrangements of dihydroflavonols are accompanied by contraction of the heterocyclic ring.

T. Swain (Cambridge), in the course of investigations on the chemical composition of some horticultural varieties of *Dahlia variabilis*, has found that the petals and leaves of some of these plants contain aglycones, which have not hitherto been discovered in this species, namely, sulphuretin, 2′ : 4 : 4′-trihydroxychalkone, naringenin, eriodictyol, quercetin and kæmpferol.

H. Erdtman (Stockholm) outlined the comparative biochemistry of the genus *Pinus*. The following flavonoid constituents have been identified in extracts of the heartwoods of these species : chrysin, tectochrysin, 6-methylchrysin, 2 : 3-dihydrochrysin, 2 : 3-dihydrotectochrysin, pinobanksin, pinobanksin 7-methyl ether, strobopinin, cryptostrobin, and strobobanksin. Here the distribution of these substances shows a positive taxonomic interest. Botanists divide the genus *Pinus* into two parts, namely, diploxylon and haploxylon. In the diploxylon species, no flavones are encountered, only flavanones occur ; in the haploxylon species, however, flavones and flavanones exist simultaneously.

F. E. King (Nottingham) has isolated derivatives of the catechin group (3-hydroxyflavans) in the heartwoods of many species of *Afzelia*. He re-examined classical views concerning the structure of such derivatives and, in the light of present stereochemical theory, he concludes that the 'epi' series should have a 'cis' configuration. Melacacidin, another component isolated from the wood of *Acacia melanoxylon*, has been identified as 7 : 8 : 3′ : 4′-tetrahydroxyflavan-3 : 4-diol and must be considered as a typical leucoanthocyanidin.

H. Schmid (Zurich) dealt with the chemistry of non-benzopyronic lactones. He described their chemistry and physical properties in relation to molecular structure. Various methods of determining the nature of the heterocyclic ring (pentagonal or hexagonal), the number and positions of the double bonds, etc., were given. He reviewed some naturally occurring well-defined types, for example, protoanemonin, kawain, nepetalactone, etc.

W. Whalley (Liverpool) spoke about sclerotiorin and rotiorin, which are pigments obtained from several strains of *Penicillium scleroteorum*. They have the empirical formulæ $C_{21}H_{23}O_5Cl$ and $C_{21}H_{22}O_5$, respectively, and both contain the same branched C_9 ethylenic chain. They almost certainly possess an α-pyrone ring characterized by the fact that the heterocyclic oxygen can be replaced by —NH— with subsequent formation of the corresponding α-pyridone.

The structure of calophyllolide, a compound isolated from the nuts of *Calophyllum inophyllum*, was discussed by Mme. Polonsky (Paris). This has the empirical formula $C_{25}H_{22}O_5 \pm CH_2$. It is an αβ-unsaturated-γ-enol-lactone having one methoxyl group. With 40 per cent potassium hydroxide it gives 5-hydroxy-7-methoxy-4-phenylcoumarin ($C_{16}H_{12}O_4$), the structure of which was confirmed by comparison with an authentic sample.

A third series of reports were devoted to analytical work.

Mme. G. Aulin-Erdtman (Stockholm) described the Δε method and its possible application to the analysis of flavone and flavone derivatives. This method is based on the modification of the ultra-violet spectra caused by ionization or other convenient chemical reactions. The change in ε-values determined at various wave-lengths (λ) is represented graphically, giving a Δε curve. This curve is a characteristic of the chromophore, which can be modified and is independent of non-reactive chromophores. The method is sometimes better than ordinary ultra-violet examination in analysing complex natural extracts.

Finally, two papers dealing with the biological properties of oxygenated heterocyclics were presented.

F. Tayeau (Bordeaux) has shown that leucocyanidol, isolated from the teguments of the arachid nut, increases vascular resistance both in animals and in men. Moreover, it possesses anti-anaphylactic properties which might be explained by its inhibitory power towards hyaluronidase. It is fixed by seric proteins, more particularly by the globulin fraction. At a certain concentration it induces formation in serum of a precipitate containing all the lipids and only very small quantities of proteins.

H. Ferrando and J. Bost (Lyons) have studied the action *in situ* of several flavones on the intestines of rabbits. Ferguson has already shown that tricin (5 : 7 : 4′-trihydroxy-3 : 5-dimethoxyflavone) strongly inhibits contraction of this organ. Its 4′-methoxy derivative, on the contrary, reduces the effects of tricin.

It will be seen from the summaries that much current work in the field of oxygenated heterocyclics was presented at this colloquium. It is to be regretted, however, that a number of centres of research in the United States, Australia, Africa and Asia could not, owing to geographical considerations, send representatives to the colloquium.

ANIMAL SOUNDS IN THE SEA

During the Second World War the ocean waters were widely explored for the first time with sensitive listening devices. Submarine eavesdroppers heard sounds which they took to be from ships where there were no ships, and many mysterious 'beeps', 'groans', 'croaks', 'crackles', 'whistles' and 'moans' came to their earphones. It was suspected that these noises were the chatter of underwater animals, and, after the War, the U.S. Office of Naval Research launched a comprehensive study of sea-animal sounds. This study has been reported by Marie Poland Fish (*Sci. Amer.*, April 1956).

Scientific workers have listened with hydrophones and recorded on tape the sounds of hundreds of species of animals, from shrimps to porpoises. The articulate denizens of the sea 'speak' a confusing variety of dialects, but each is distinctive, and with experience it is possible to identify the kind of animal by its sounds, as one recognizes a familiar voice on the telephone. Listening to tropical fishes in the waters of the Caribbean, trained recorders can recognize them on approach before they come into view. Fishes and other sea animals have no vocal organs : they make sounds in diverse and intriguing ways which sometimes involve a large part of the anatomy.

One group produces sound by vibrating the walls of their balloon-like air bladder, the bladder acting like a sound-box or drum. The toadfish, for example, sets up vibrations of its bladder by means of muscle contractions, and the sound emitted ranges from a grunt to a 'fog-horn' boom. Experiments have shown that the sound originates in the air bladder. When the bladder was removed, the fish could produce no sound. But the air bladder alone, placed in a jar of sea water and stimulated by electricity, emitted grunts which were typically 'toadfish' to the ear.

A second class of sound-makers produce noises by scraping one body part against another; this is particularly common with the 'teeth-grinders'. The squirrelfish, for example, grinds together toothed areas in the back of its mouth, called gill teeth, and so generates a sound which is amplified by the adjacent air bladder and becomes a rasping grunt.

One of the most puzzling sounds which was encountered was that of the sculpins, a family of spiny sea fishes like the freshwater bullhead. These fishes issue a dull low-pitched drone which suggests the hum of an electric generator. The sculpin has no air bladder, and it was difficult to understand how the fish produced its sound. Examination of its anatomy and recent experiments suggest that the noise is made by rapid vibration of muscles attached to certain bones in its skeleton.

The most garrulous fish is the sea robin. Most fishes try to make a silent escape when something strange approaches. This is not the case with sea robins, which keep up a barrage of grunting and cackling—disturbed or undisturbed. A tame sea robin in an aquarium clucks softly when stroked, like a purring cat, but if handled too much will break away in seeming annoyance and emit a burst of noise. Other fishes appear to be noisy only when noise is called for. With the approach of a ship, fishes usually cease their chatter instantly.

Fish apparently make noises for a great variety of reasons. They use sound to communicate. Squirrelfishes, which are inclined to be nocturnal; eels and catfishes, which live in muddy, murky waters; croakers, which become most active after sunset—these and similar species must find sound useful for aggregating. Many fish become most loquacious during the spawning season.

Competition seems to be a common stimulus to sound. Sprinkling of food in a tank of sonic fishes incites a general noisy commotion.

Experiments have indicated that sea horses may use sound for orientation. During the first few days of captivity they make vigorous snapping noises, apparently associated with the strangeness of the new environment.

Of the more primitive forms of life, the shrimps make most noise. The combined popping of thousands of shrimps in their unseen beds makes a crackling chorus day and night. Experiments indicate that this noise accompanies the ejection of jets of water which the shrimps use for offence and defence.

In the case of marine mammals, the noises of whales and porpoises may be heard all over the oceans. The noises have been described as "propeller or screw noises", and clucking and squealing sounds covering the whole sound band and 'pings' suggestive of echo-ranging.

Learning sea sounds and languages has certain practical uses. Already the U.S. Navy has found the research helpful for predicting underwater sound conditions in strategic areas, for developing underwater acoustic gear and for training sonar operators. Commercial fishermen are using acoustic finders to locate schools of fish. They would like 'hearing aids' which could spot concentrations of food fish, identify them by their sounds and track their movements in bird-dog fashion. It may eventually be possible to use stationary, remotely controlled listening posts, comparable to sonar buoys, which will detect and broadcast the position of migratory fishes.

CHELATING AGENTS AS PLANT GROWTH SUBSTANCES

A POSSIBLE CLUE TO THE MODE OF ACTION OF AUXIN

By Dr. O. V. S. HEATH and Miss J. E. CLARK

Research Institute of Plant Physiology, Imperial College of Science and Technology, London

THE observation which gave rise to this work was made during an attempt to prevent the inhibiting effect of chromatographic paper on the growth of wheat coleoptile sections in the 'straight growth' test as modified by Hancock and Barlow[1]. It was found that acid-washed paper, treated with ethylenediaminetetra-acetate (EDTA) and washed, caused significantly more growth than occurred in the complete absence of paper. An experiment was therefore carried out without any paper, in which EDTA was given at concentrations of zero and 10^{-10} to 10^{-5} *M*, both with and without 10^{-5} *M* 3-indolylacetic acid (IAA). It was found that after 19 hours 10^{-5} *M* EDTA alone gave practically the same increment of growth compared with controls as did 10^{-5} *M* IAA alone, and even 10^{-10} *M* EDTA alone apparently caused some increase.

In this experiment the interaction between IAA and EDTA did not approach statistical significance ($P \simeq 0{\cdot}2$), consistent with the hypothesis that their effects were independent and additive.

Similar experiments were then carried out using seven chelating agents, of very various molecular structure, at concentrations of zero, 10^{-9} *M*, 10^{-7} *M* and 10^{-5} *M* in combination with zero and 10^{-5} *M* IAA. It was found that all the agents tried could act as growth substances, namely, EDTA, uramildiacetic acid (UDA), anthranilic acid diacetic acid (AADA), nitrilotriacetic acid (NTA), iminodiacetic acid (IDA), 8-hydroxyquinoline (8HQ) and sodium diethyldithiocarbamate (DIECA). It was found that although DIECA, a heavy metal enzyme inhibitor, could act as a growth-promoting substance, another such inhibitor, namely, potassium cyanide, which was not a chelating agent, depressed growth at the same concentrations. In this series of experiments no indications of interactions with IAA were found,

Table 1. Mean Length (cm.) of Wheat Coleoptile Sections, originally 1 cm., after 19 hours at 25° C. (1.12.55). Five Replicates, each of Five Coleoptiles

	EDTA:	0 *M*	10^{-10} *M*	10^{-9} *M*	10^{-8} *M*	10^{-7} *M*	10^{-6} *M*	10^{-5} *M*
IAA	0 *M*	1·81	1·91	1·91	1·93	1·95	2·02	2·05

		γγDP			**2·09**	**2·06**	**2·03**	**2·03**		
19.2.56	0	Nil	1·72	1·75	1·75	1·74			0·029	0·039
		8HQ	**1·82**	**1·84**	**1·88**	**1·89**				
		2HQ	**1·75**	**1·71**	**1·71**	1·73				
	10^{-5}	Nil	2·06	2·06	2·08	2·07				
		8HQ	**2·10**	**2·10**	**2·15**	**2·12**				
		2HQ	2·08	2·07	2·06	2·06				
1.2.56	0	Nil	1·84	1·85	1·84	1·85			0·031	0·041
		DIECA	**1·89**	**1·97**	**1·92**	1·88				
		KCN	1·85	1·85	**1·74**	**1·73**				
	10^{-5}	Nil	1·98	1·98	1·98	1·98				
		DIECA	**2·05**	**2·04**	**2·09**	**2·05**				
		KCN	2·00	1·99	1·98	1·99				

Values in heavy type differ significantly from the corresponding control (nil). Key to agents: NTA = nitrilotriacetic acid; IDA = iododiacetic acid; AADA = anthranilic acid diacetic acid; UDA = uramildiacetic acid; ααDP = αα-dipyridyl; γγDP = γγ-dipyridyl; 8HQ = 8-hydroxyquinoline; 2HQ = 2-hydroxyquinoline; DIECA = sodium diethyldithiocarbamate; KCN = potassium cyanide

except for 8HQ and DIECA, which both tended to cause less growth at 10^{-5} *M* than at 10^{-7} *M* in the presence of IAA but not in its absence.

At the suggestion of Dr. W. R. Rees, of this Institute, a similar experiment was carried out using 8HQ and its two analogues α-naphthol and quinoline. The chelating agent 8HQ increased growth as before, while the non-chelating analogues depressed growth in all concentrations used, whether with or without IAA.

It seemed clear that the various chelating agents must act as growth substances by virtue of their chelating properties, and this raised the possibility that IAA might act in the same way. We consulted Dr. E. R. Roberts, of the Chemistry Department, Imperial College of Science and Technology, who kindly informed us that in his view the distance between the imino and carboxyl groups of IAA was suitable for chelation to occur with the formation of a seven-membered ring. Such chelate compounds would be most stable with heavy metal ions such as Cu^{++} or Co^{+++}. Even if true chelates were not formed by IAA, complex formation would certainly be expected.

Nearly all the above preliminary experiments have since been repeated using a revised technique for setting up the coleoptile sections in the treatments, which gives consistently a standard deviation for one 'replication' (the mean of five coleoptile sections) of about 0·02 cm. or 1 per cent of the mean length after 24 hours. This has very greatly improved the precision of treatment comparisons, and therefore numerical results from these later experiments only are presented in Table 2.

All the chelating agents significantly increased growth, both in the absence and presence of IAA. In only one case did a non-chelating analogue (just) significantly increase growth (2HQ at 10^{-9} *M* without IAA), and here the corresponding 'control' value was an unusually low one, being 'significantly' less than two other 'controls'; this may well have been a fortuitous difference therefore. In a number of cases the non-chelating analogues actually depressed growth, and this was again also true of potassium cyanide. It is not proposed to discuss the interactions with IAA at this juncture.

Before carrying out the experiments recorded in Table 2, it had seemed necessary to test the possibility that all the observed effects of chelating agents in our experiments (including perhaps even those of IAA) might be due to their removing harmful metal ions from the distilled water used. Distilled water from our usual source (a tinned boiler and 'Pyrex' glass condenser) was compared with water of very low ion content from a 'Biodeminrolit' mixed-bed ion-exchange resin column. Differences in growth between sections in the two samples of water were extremely small and entirely non-significant whether in the absence or presence of IAA and EDTA (10^{-5} *M*) alone or together. In this rather precise experiment a highly significant ($P < 0·001$) interaction of IAA and EDTA was found such that the combined stimulating effect was less than the sum of the effects of the agents acting separately (Table 3).

Table 3. MEAN LENGTH (cm.) OF WHEAT COLEOPTILE SECTIONS, ORIGINALLY 1 cm., AFTER 24 HOURS GROWTH AT 25° C. FIVE REPLICATES, EACH OF FIVE COLEOPTILES (18.1.56)

EDTA:		0 *M*	10^{-5} *M*
IAA	0 *M*	1·84	2·09
	10^{-5} *M*	2·11	2·24

Significant difference (P 0 05) = 0 02; (P 0·001) = 0 03

On the hypothesis that the two agents were acting in exactly the same way, an interaction in this sense would be expected if response tended to be linear with log concentration rather than with concentration itself. It should be noted, however, that the response to EDTA alone was just significantly less than that to IAA alone, although the difference in response was only 8 per cent.

Further experiments were designed explicitly to test the hypothesis that EDTA and IAA were identical in their action. The first two of these, with mixtures of the two agents in proportions 0 : 100, 25 : 75, 50 : 50, 75 : 25 and 100 : 0, at total concentrations of 10^{-7}, 10^{-6}, 10^{-5}, 10^{-4} *M* and 10^{-8}, 10^{-7}, 10^{-6} *M* respectively, showed in all cases somewhat more growth after 24 hours with the higher proportions of IAA. It seemed possible that this might be due to slower penetration of the EDTA into the tissues, and in two further experiments growth-time studies were made. In these, mixtures in the proportions 0 : 100, 50 : 50 and 100 : 0 at a total concentration of 10^{-6} *M* were used; fresh samples of coleoptile sections were measured at 3, 6, 12, 24 and 48 (or 36) hours. At 48 hours, in the first of these experiments, signs of morbid changes were observed; the results of the second experiment, therefore, are presented in Fig. 1.

It will be seen that the curve for pure EDTA rose more slowly than that for pure IAA, consistent with the hypothesis of slower penetration, but that by 36 hours the total growth was almost exactly the same. The significance of the interaction between the two agents can be tested by that of the quadratic coefficient in the regression of length on proportion of IAA; a coefficient not significantly different from zero is consistent with identical internal action of the two agents and a linear (or additive) response to amount penetrated. This coefficient varies very significantly with time, and most interest is attached to the interaction at 36 hours when penetration by both agents was probably almost complete. Here the combined effect in the 50 : 50 mixture was to give less total growth ($P < 0{\cdot}001$) than in either of the pure solutions, thus disproving the hypothesis of identical internal action of the two agents. On the other occasions, the effects were apparently additive at 3, 12 and 24 hours; but at 6 hours the combined agents again gave less growth than the mean of that in the two pure solutions.

It should be noted that for every chelating agent tried the greatest coleoptile extension obtained at 24 hours with the agent alone was significantly less than with 10^{-5} *M* IAA alone (Table 2). In some cases, at least, this might well be due to slower penetration, as with EDTA.

The results so far discussed are all for coleoptile growth; but three experiments on root growth have been carried out, in which intact wheat seedlings were grown in solutions of EDTA and IAA alone and combined. The results for the second and third of these experiments are presented in Tables 4 and 5. The solutions were made up in distilled water, without nutrients, and changed every 3 days. After 8 or 9 days growth the total length of roots on each plant and its longest root were measured. The treatment means for total length only are presented, as the longest root data showed very similar effects.

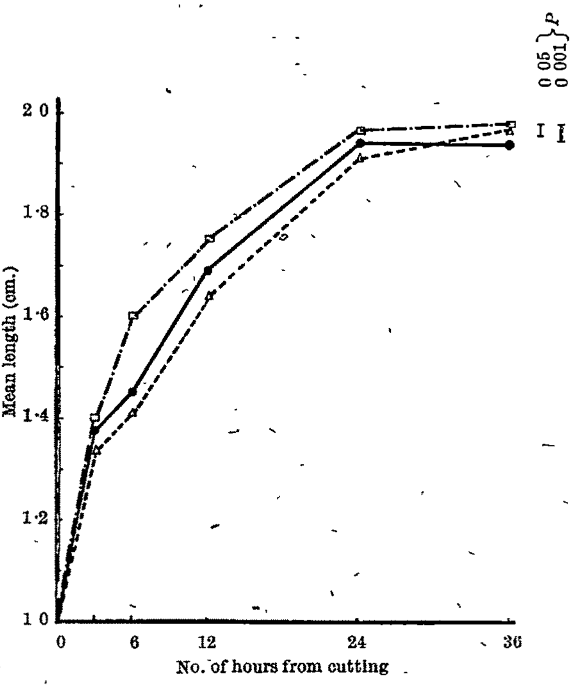

Fig. 1. ●—, 50 . 50 EDTA, IAA; □—·—, IAA only (10^{-6} *M*); △----, IAA only (10^{-6} *M*)

IAA or EDTA alone show essentially similar effects; in fact, the two agents give almost the same results throughout the experiments. There is, however, evidence of a most remarkable mutual antagonism; thus the inhibitory effect of a 10^{-5} *M* concentration of *either* agent is completely or almost completely removed by the presence of a 10^{-9} or 10^{-11} *M* concentration of the other (that is, at one-hundred-thousandth or one-millionth the concentration). The underlying mechanism of this extraordinary mutual antagonism is obscure, and it is not proposed to speculate about it here. Clearly, however, although the main conclusions would be unaltered by interchanging the names IAA and EDTA in the tables, the mode of operation of the two agents cannot be identical; for adding 10^{-11} *M* IAA to 10^{-5} *M* IAA could scarcely prevent inhibition. It must be remembered that in coleoptile growth we have

Table 4. TOTAL LENGTH OF ROOTS (cm. per plant) OF WHEAT SEEDLINGS AFTER EIGHT DAYS GROWTH. TWO REPLICATES, EACH OF THREE PLANTS (23.3.56)

EDTA:		0 *M*	10^{-11} *M*	10^{-9} *M*	10^{-7} *M*	10^{-5} *M*
IAA	0 *M*	*25·1*	*25·6*	*24·9*	*24·3*	12·5
	10^{-11} *M*	*26·1*	*27·3*	*24·6*	*25·8*	*24 1*
	10^{-9} *M*	*22 5*	*26·4*	*23·0*	*22·6*	*25 2*
	10^{-7} *M*	13 2	*24·4*	21·5	15 0	13 5
	10^{-5} *M*	12·1	*23·5*	20·4	12·7	10 9

Significant difference (P 0·05) = 2·64; (P 0·001) = 4·79
Values in *italics* do not differ significantly from that for water alone

Table 5. TOTAL LENGTH OF ROOTS (cm. per plant) OF WHEAT SEEDLINGS AFTER NINE DAYS GROWTH. TWO REPLICATES, EACH OF THREE PLANTS (21.4.56)

EDTA:		0 *M*	10^{-11} *M*	10^{-9} *M*	10^{-7} *M*	10^{-5} *M*
IAA	0 *M*	*24 9*	*26 0*	21 0	16·3	8 9
	10^{-11} *M*	*25·8*	*26·3*	*24·2*	22·5	22·5
	10^{-9} *M*	*24·7*	*25·2*	*24·8*	22·0	21·3
	10^{-7} *M*	16·8	21·6	*22·8*	20·2	15 4
	10^{-5} *M*	6·5	*23·8*	*23 0*	16·1	11·3

Significant difference (P 0·05) = 2 39; (P 0·001) = 4·32

Values in *italics* do not differ significantly from that for water alone been concerned with stimulation, but that here nhibition is the main effect; the slight stimulation at 10^{-11} *M* fails to reach significance even for the two agents together. It seems likely that the pathways of stimulation and inhibition may be entirely different, and thus quite different types of interaction between IAA and EDTA for coleoptile and root growth might be expected. Experiments on inhibition of coleoptile growth by supraoptimal concentrations would be of interest and it is hoped to undertake these shortly.

The first root-growth experiment, with a different variety of wheat, showed a similar type of mutual antagonism between EDTA and IAA, but here a concentration of 10^{-7} *M* of one agent was needed to remove the inhibition due to a 10^{-5} *M* concentration of the other.

During the course of this investigation, between the carrying out of the preliminary experiments and those with the revised technique, Prof. T. A. Bennet-Clark very kindly showed us the proof of his paper at the Wye Growth Substance Conference[2], in which he reports the finding that EDTA in concentrations from 10^{-5} *M* to 10^{-3} *M* can act as a growth promoter in the straight-growth test and suggests that the calcium metabolism of the cell wall is concerned.

All the biological evidence presented here would seem consistent with the hypothesis that IAA acts on growth in the same way as a chelating agent, either by forming true chelate compounds or complexes of some sort, although its mode of operation cannot be *identical* with that of EDTA in view of the peculiar interactions which occur between the two; as yet, however, we have obtained no experimental chemical evidence of such complex formation by IAA. If it in fact acts as a growth substance by virtue of complex-forming properties, there would seem to be three ways in which it might do so: first, it might act by removing metal ions which would otherwise restrict growth, as in the suggested effect of EDTA in removing calcium from pectate in the cell wall[2], though chelation of heavy metals would seem more probable; secondly, it might act as an enzyme inhibitor, either by removing metals needed as coenzymes or perhaps by 'covering up' metals in prosthetic groups. In this connexion it may be noted that Smith, Lumry and Polglase, cited by Martell and Calvin[3], found that IAA strongly inhibited the Mg-stimulated enzyme carboxypeptidase. Thirdly, work by Calvin[4] and Weller and Mills[5] has shown that a complex of an acetate and two quinoline molecules with copper can transfer hydrogen and thus function as a catalyst for the hydrogenation of suitable hydrogen acceptors—IAA might form complexes which could function in a similar manner. It will be noted that in the first two suggestions IAA would be inhibiting some aspect of metabolism; in the third, it would be itself contributing positively to metabolism. If IAA could function in two or all three of these ways, its extraordinary range of known effects on growth and development would be less surprising.

Synthetic auxins in general may also act through their complex-forming activities. Thus, for example, 2-4-dichlorophenoxyacetic acid is, in Dr. E. R. Roberts's opinion, more likely to form metal complexes than phenoxyacetic acid (which is inactive[6]). This would explain the very wide variety of compounds which are found active, including in the present work many which do not conform to the structural pattern generally postulated for auxins (for example, by Thimann[6]), and would also account for their similar but wide range of effects.

Further work, including experiments with various metallic ions, is in progress, and detailed publication will follow in due course.

We are grateful to Drs. W. R. Rees and J. Edelman, of this Institute, for helpful suggestions and discussions, in particular to the former for suggesting the experiments with analogues of 8-hydroxyquinoline; also to Dr. E. R. Roberts, of the Chemistry Department, Imperial College, for providing the theoretical evidence that indolylacetic acid is likely to act as a chelating or complex-forming agent.

AN UNORTHODOX VIEW OF THE WEATHER

By Dr. E. G. BOWEN

Division of Radiophysics, Commonwealth Scientific and Industrial Research Organization, Sydney, Australia

FOR more than a generation the concept of the general circulation of the atmosphere has played a dominant part in the science of meteorology. It has helped explain many of the mysteries of weather phenomena and been responsible for great advances in this field of endeavour. The working tool of the forecasting meteorologist is the synoptic chart, which shows the pressure distribution over the surface of the Earth at any given time. Being based on measurements of barometric pressure at many points on the Earth's surface, the chart represents a very real physical situation. It gives vital information on the movement of air masses and has become the most important aid to forecasting the weather. It is especially useful for aircraft, which have the problem of moving around within those air masses. But it has its weaknesses, particularly on the question which is of most interest to the man in the street, namely, the forecast of whether it will rain to-morrow.

The method of preparing a forecast of rain from the chart has been variously described as 'a matter of intuition' or 'an empirical process which draws on past experience'. How is it that intuition and empiricism come into this important function and how can they be taken out? The forecaster has available to him a large number of physical measurements collected from a wide network of observing stations. Some of these, like the instability of the

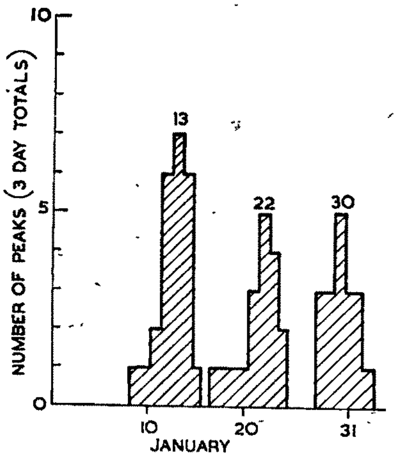

Fig 1. Histogram of the dates in January on which the concentration of freezing nuclei was observed to be high in the three years 1954, 1955 and 1956

atmosphere and the amount of moisture aloft, are closely related to whether clouds will form. But a measurement which has a direct physical connexion with the formation of rain is lacking.

It has been known for some time that such a measurement is possible; but its importance has not been fully appreciated. In the study of cloud physics, it is well established that the number and properties of the freezing nuclei present in the atmosphere determine whether rain will form in a supercooled cloud. Freezing nuclei, in this context, may be defined as particles on which ice crystals can grow from the vapour phase, or else materials which in solution in a water droplet or in contact with it will induce it to freeze. Measurement of the concentration of freezing nuclei and the temperature at which they become active is not easy; but if such measurements are made in aircraft or at sites which are free from the interfering effects of dust from terrestrial or industrial sources, several interesting facts emerge. It is found, for example, that while measurements of the concentration of freezing nuclei are consistent among themselves in one area or over a few hours at a time, changes of several hundred to one are possible from one day to the next. Many of the quantities used in meteorology, such as barometric pressure, vary at most by a few per cent and can only be linked with the formation of rain by what is admitted to be a subjective process. By contrast, the number of freezing nuclei in the atmosphere has a direct bearing on the formation of rain. It may vary by orders of magnitude from one day to the next; but the unfortunate forecaster is unaware that such a change has taken place. Could this be the reason why forecasts of rain sometimes go wrong? Could a sudden and unobserved increase in freezing nucleus concentration lead to the development of rain which did not appear likely from the synoptic chart?

Table 1. Dates of High Counts of Freezing Nuclei in January 1954–56

Year	Place	Date (January)		
1954	Sydney	12 14	22	31
1955	Sydney	13	23	29
	Hawaii	10	23	29
	Arizona	—	—	—
	Panama	13	18	31
1956	South Africa	13	—	29
	West Australia	13	22	Feb. 1
	Sydney	—	—	—
	San Francisco	13	21	—

For a proper assessment of the role of freezing nuclei, measurements are needed in many parts of the world. These are just beginning to be made on a routine basis, and they already point to a further intriguing possibility—that the sudden changes occur at almost identical times in different parts of the world. Smith, Kassander and Twomey[1] have reported measurements made in Sydney in January 1954 and again in Sydney, the Hawaiian Islands and Panama in January 1955, which showed there were sudden increases in the number of freezing nuclei on the dates given in the first part of Table 1. Similar measurements made in Arizona showed no significant variations. In January 1956 there were no increases in Sydney comparable in magnitude with those of previous years; but measurements in South Africa, Western Australia and the west coast of the United States showed marked increases on the dates shown in the latter part of Table 1. I am indebted to Dr. S. C. Mossop, of the National Physical Laboratory, Pretoria, Dr. E. K. Bigg, of the Radiophysics Laboratory, and Dr. R. N. Bracewell, of Stanford University, for permission to quote these results. The peaks do not always appear in all localities; but when they do occur, they are nearly simultaneous in widely separated parts of the globe. Furthermore, they seem to recur on approximately the same dates from year to year. A histogram giving the dates on which the freezing nucleus counts were high is given in Fig. 1, indicating that for the three years 1954,

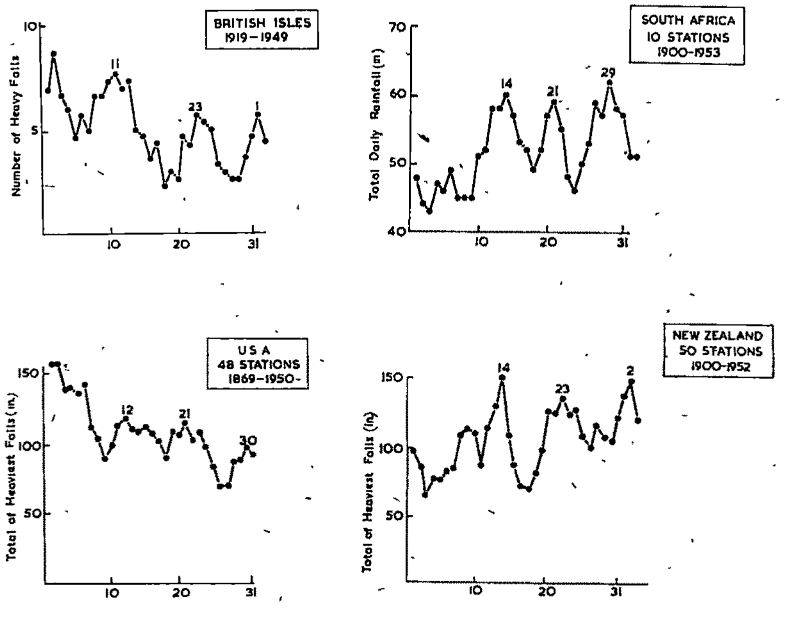

Fig. 2. The January rainfall of four countries in widely separated parts of the world

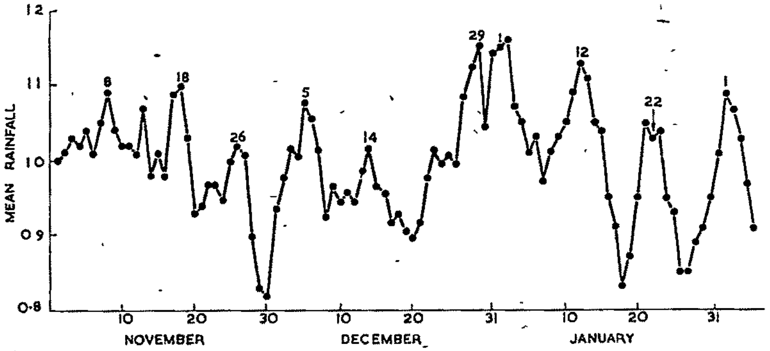

Fig 3. The mean rainfall of November, December and January for three hundred stations distributed over the globe

1955 and 1956 the maxima occurred on January 13, 22 and 30.

This behaviour is strikingly similar to that of the rainfall in many parts of the world. As reported in a recent publication[2], if the records of a large number of stations are examined, there appears to be a preference for heavy falls of rain to occur on certain dates. In Fig. 2 is given the number of falls of rain exceeding 2½ in. in 24 hours in January in the rain-gauge network of Great Britain for the period 1919–49. It shows distinct variations from one day to the next. In the remaining curves are corresponding observations for three other regions of the globe, namely, forty-eight stations in the United States, ten in South Africa and fifty in New Zealand. In each case the stations were chosen by officers of the respective weather bureaux to be representative of the whole country. There appears to be a remarkable agreement between them, in spite of the widely different climatic regimes which exist in these areas, and the fact that they refer to winter-time in one hemisphere and summer-time in the other. There are three rainfall peaks which appear within a few days of each other on all four curves and, furthermore, they are grouped around the dates January 13, 22 and 30, on which the concentration of freezing nuclei in the atmosphere has been observed to have high values.

The close relationship between the January rainfall of widely separated regions which is exhibited in Fig. 2 is not in accord with conventional meteorological ideas. As it is so difficult to explain the present effect on ordinary climatological grounds, let us look outside the immediate boundaries of meteorology for the explanation. The clues are clear-cut—the effect appears to be one which occurs almost simultaneously over the globe, which suggests an extra-terrestrial phenomenon; and it takes place on particular calendar dates, which suggests an association with meteor showers.

Table 2. Comparison of Dates of Meteor Streams and Rainfall Peaks

Date of rainfall peak	Meteor stream	Date	Time difference (days)
Nov. 8	Giacobinids	Oct. 9	30
18	Orionids	Oct 20–23	29
26	Not known with certainty		—
Dec. 5	Taurids	Nov. 3–10	32
14	Leonids	Nov. 16	28
29	Bielids I	Nov. 27→15	—
Jan. 1	Bielids II	Dec. 2	30
12	Geminids	Dec. 13	30
22	Ursids	Dec. 22	31
Feb. 1	Quadrantids	Jan. 3	29

Relation to meteor showers. The Earth in its orbit is known to pass through streams of dust which exist in vast elliptical orbits around the Sun. The dust includes a wide range of particle sizes. The large ones burn up on entering the atmosphere and appear as visible meteors; the smaller particles do not have enough energy to be consumed and fall slowly into the lower atmosphere. Svestka[3] has shown that meteoritic dust takes between thirty and forty days to fall from the top of the atmosphere to the troposphere. It may be significant that there are three prominent meteor showers about thirty days before the rainfall peaks, namely, the Geminids of December 13, the Ursids of December 22 and the Quadrantids of January 3.

It appears, therefore, that the rainfall peaks might occur about a month after the meteor showers. This possibility can be tested in an elementary way by examining the rainfall of a somewhat longer period than that given in Fig. 2. In Fig. 3 is a curve of the mean rainfall for the three months November, December and January for a period of about sixty years. The curve is for approximately three hundred stations distributed over the globe, and includes those already referred to in the United States, Great Britain, South Africa and New Zealand, together with fifty stations from Australia, thirty-two from Japan and five from the Netherlands. The dates of ten of the most prominent peaks are listed in the first column of Table 2, together with a list of the meteor showers which appear to correspond. The only rainfall peak which is not associated with a well-known meteor shower is that of November 26; nevertheless, Ellyett and Roth[4] have reported previously unsuspected meteor activity in the southern hemisphere approximately a month before this date. In the interests of brevity, the results in this table are only given in the barest outline, and a full treatment is in course of publication in the meteorological literature.

In the final column of Table 2 is the difference in time between the meteor showers and rainfall peaks, and it is seen to have a mean value of 30 days, with greatest departures from this value of ± 2 days. The hypothesis has therefore been advanced that dust from meteor streams falls into the cloud systems of the lower atmosphere, nucleates them and causes exceptionally heavy falls of rain thirty days after the dust first entered the atmosphere.

There are several aspects of this hypothesis which are difficult to accept, and many questions arise. Why should meteoritic dust be so active as a nucleating agent? Why does the time of fall appear to be so consistent from one shower to the next? And why is the effect on rainfall confined to such a few days? As yet these are without answer; but there is already enough evidence about the reality of the effect to call for a thorough investigation of the physics of the phenomenon and a careful assessment of its impact on the day-to-day problems of meteorology.

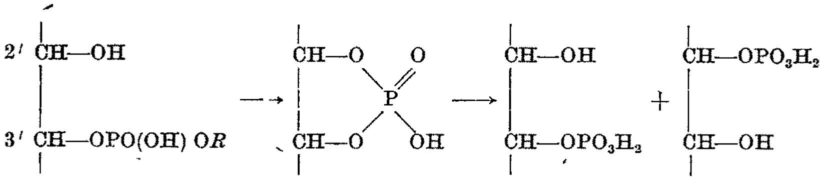
Hydrolysis of Esters of Monoribonucleotides

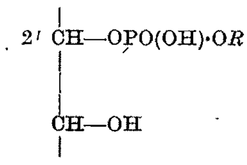
CONSIDERABLE attention has been paid in recent years to the hydrolysis of ribonucleic acids to mononucleotides. It was shown[1,2] that alkyl esters of the 2′- and 3′-monoribonucleotides (partial formula I ; R = alkyl) provided simple model substances which could be used for a more precise study of the mechanism of hydrolysis. The overall process, effected by acid or by alkali, results in a conversion of (I) to a mixture of (III) and (IV). Both procedures involve the unstable cyclic ester intermediate (II), which is then hydrolysed to the isomeric mononucleotides (III) and (V). Since the conversion of (I) → (II) is formally a trans-esterification[3], it seemed possible that the analogous process (I) → (V), that is, migration of the alkyl phosphate residue without loss of R, might also occur simultaneously.

When cytidine-3′ benzyl phosphate (I ; $R = CH_2.C_6H_5$) is partially hydrolysed by 0·5 N sodium hydroxide solution, the ester recovered can be shown by ion-exchange chromatography to contain none of the corresponding 2′-ester (V). Other experiments show that no observable conversion of a 2′-methyl ester (V ; R = Me) to the 3′-ester (I) occurs under similar conditions. Thus under alkaline hydrolytic conditions, no migration of the alkyl phosphate group occurs. This result appears to imply that the step (I) → (II) involves a transition state which may be represented by (VI), and not a discrete molecule such as (VII) analogous to that involved in the alkaline hydrolysis of carboxylic esters[4].

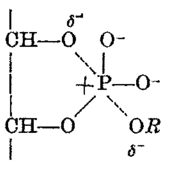
After partial acid hydrolysis, however, analysis of the remaining ester reveals that migration of the alkyl phosphate group occurs to a significant extent. Thus when hydrolysis of (I ; $R = CH_2Ph$) is carried to 53 per cent of completion; (V) accounts for 25 per cent of the remaining ester. Of direct significance for ribonucleic acid chemistry is the finding that the dinucleoside phosphate adenosine-2′ uridine-5 phosphate[5] (V ; R = uridine-5′ residue) yields a proportion of the rearranged product adenosine-3′ uridine-5′ phosphate. Qualitative observations on the rate of hydrolysis indicate that the reaction is catalysed by acid. The results are accommodated if protonated species derived from intermediates of type (VIII) or (IX) are postulated, the latter arising directly or *via* (VIII). These could then lead by P—O fission either to (I), (II) or rearranged ester (V). The mechanism of the rearrangement (I) → (V) is presumably essentially similar to that of the acid-catalysed migration of phosphate in the mononucleotides (III) and (IV).



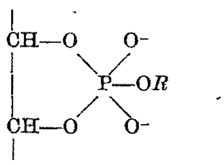
(I) (II) (III) (IV)



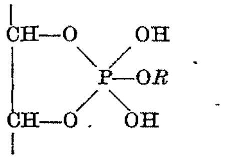
(V)



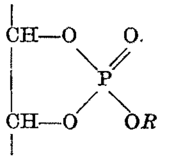
(VI)



(VII)



(VIII)



(IX)

Baer and Kates[6] have suggested a similar migration during the acid hydrolysis of α-glycerophosphorylcholine and -ethanolamine to account for optical rotation changes. They, and Long and Maguire[7], also conclude that alkylphosphoryl migration occurs during alkaline hydrolysis ; but the present observations appear to invalidate this.

It is intended to discuss our experiments in more detail elsewhere in relation to other work on phosphate ester hydrolysis. The purpose of the present communication is to indicate their relevance to ribonucleic acid hydrolysis. Partial acid hydrolysis has been used for preparing a variety of oligonucleotides[8]. The internucleotidic linkage in ribonucleic acids is at present considered to involve a phosphodiester bridge exclusively between the 3′- and 5′-positions in adjacent ribonucleoside residues[2]. On the above evidence, however, partial acid hydrolysis of such a structure must be expected to give rise to oligonucleotides, a proportion of which will have a 2′ : 5′-internucleotidic linkage. The isolation of such a substance will, in itself, afford no evidence for a 2′ : 5′-linkage in the ribonucleic acid structure. Furthermore, present enzymic methods for polynucleotide structure analysis, if applied without realization of the possibility of isomerization of the internucleotidic linkage, may lead to erroneous conclusions. This follows from the fact that the nuclease-type enzymes (for example, ribonuclease) have differing specificities for purine and pyrimidine nucleoside sites in the molecule, but all those studied have shown a specific requirement for a 3′ : 5′-internucleotidic linkage[9]. The validity of the use of such nucleases for sequence determination in oligonucleotides rests on the assumption that the 3′ : 5′-internucleotide linkage is preserved unchanged during the hydrolysis of the nucleic acid ; it loses its validity if a change from 3′ : 5′- to 2′ : 5′- can occur. Such methods should be supplemented by the known hemical degradation, which can distinguish between $3' : 5'$- and $2' : 5'$-phosphodiester linkage[10].

Ionophoresis of Oligosaccharides as N-Benzylglycosylammonium Ions

Filter-paper ionophoresis is now being widely used for separations of mixtures of neutral sugars, which are converted into charged molecules by the formation of borate complexes[1]. This excellent method provides a far more rapid separation of isomeric components which possess appropriate structural differences than does filter-paper chromatography; and at the same time, deductions can be made about the probable structure of an unknown sugar from its rate of migration. It does, however, suffer from a disadvantage when compared with filter-paper chromatography, inasmuch as it does not give any indication of the molecular size of an unknown oligosaccharide. We now report a different method of filter-paper ionophoresis which readily yields this information; it is to be regarded as complementary to the borate process. When both methods are used in conjunction, much information about a new product can be gained very rapidly.

This alternative method of ionophoresis is a development of the technique of filter-paper chromatography in which reducing sugars are converted on the paper into N-benzylglycosylamines[2]; in this case a charge is afterwards placed on the nitrogenous derivative by using a strongly acid solution as the medium during electrolysis. In the general method the reducing sugar is spotted on to a strip of Whatman No. 3 filter-paper, and a spot of a solution of benzylamine (1 c.c.) in methanol (9 c.c.) and 10 *N* formic acid (5 c.c.) is superimposed. The paper is heated at 95° for 5 min. and then subjected to ionophoresis at 600 V./55 cm. for 6 hr. in an electrolyte (*p*H 1·8) composed of a mixture of 5 per cent aqueous sodium hydroxide (600 c.c.) and 90 per cent formic acid (400 c.c.). The paper is dried to remove all formic acid, and the spots are detected with alkaline silver nitrate[3] or periodate[4]. The mobility is expressed as the ratio between the distance which separates the N-benzylglycosylammonium ion from the unchanged sugar and the distance which separates the N-benzylglucosylammonium ion from unchanged glucose. It is quite convenient to measure these distances because the reaction between the sugar and the benzylamine is not complete (cf. ref. 2). Typical results are given in Table 1.

Table 1

Sugar	Mobility*
Pentose	1·09–1 15
Hexose	1 00
Heptose	0 91
Hexose disaccharide	0 71–0·78
Hexose trisaccharide	0·59–0 63
Hexose tetrasaccharide	0 49–0·51
Hexose pentasaccharide	0·42
Hexose hexasaccharide	0·33

* Defined in text

It will be seen that the mobility bears an inverse relationship to the molecular weight of the ion; to the first approximation, it is independent of the stereochemistry of the sugar and also of the positions of the linkages in a higher saccharide. Full details of this work, including the experiments which led to the development of the general method and studies with amines other than benzylamine, will be reported later. The work was supported by a grant from the Nuffield Foundation.

Ion-Exchange Preparation of Low-Silica Hydroxide Solutions for Colorimetric Determinations of Total Silica

Attempts to determine small concentrations of total silica colorimetrically by applying the method of Straub and Grabowski[1], following solubilization of the silica by boiling with hydroxide, have been frustrated by the interference of the silica present in either the sodium or potassium hydroxide used as the solubilizing agent. In studying this problem, the possibility of preparing a hydroxide solution by passing a salt solution through the hydroxide-form of a quaternary-base ion-exchange resin was investigated. The fact that complete conversion from the salt to the hydroxide is not required for the analytical method is a recommendation of this approach; a salt solution more concentrated than is normally amenable to ion-exchange treatment may be used as the starting material in order to produce a moderately concentrated hydroxide solution.

A quaternary ammonium-type anion-exchange resin ('Amberlite *IRA*-400') was used in the preparation of the caustic solutions. A small column of the resin was prepared in a 1- or 2-in. diameter polyethylene pipe. The resin was converted to the hydroxide-form by treating it with six volumes/volume resin of 4 per cent sodium bicarbonate solution followed by six volumes/volume resin of 4 per cent sodium hydroxide solution both at a rate of 0·15 ml./ml. of resin/min. The column of resin was then rinsed to a *p*H of 9·5 with deionized water.

Solutions of *N* potassium chloride and of *N* potassium sulphate have been used as starting materials for the preparation of caustic solutions. The potassium salts were selected in preference to the corresponding sodium salts because they contained smaller amounts of silica. The salt solutions were passed through the resin at the rate of 0·15 volume/volume resin/min. A total of one volume of salt solution per volume of resin was treated in each cycle. Regeneration of the column between cycles was carried out with sodium bicarbonate and sodium hydroxide by the same method as the original regeneration. In each cycle the hydroxide effluent was collected in five equal fractions and analysed for silica content and for their hydroxide content. Typical results are given in Table 1.

Table 1. CHARACTERISTICS OF HYDROXIDE SOLUTIONS PREPARED VIA ION EXCHANGE

Cut 4	5	—	0·29	0·10
Cut 5	5	—	0·24	0·10

* Glass column.
† Only sodium hydroxide used as regenerant.

It may be seen that the quality of the effluent hydroxide increases with increasing number of regeneration cycles. The solution prepared in cycle 4, when used for solubilizing silica at a ratio of 1 ml./50 ml. of water sample, contributes only 0·002 p.p.m. to the final solution being analysed. This is below the present limits of detection of silica by colorimetric methods.

The above procedure is now being employed in a study of the concentration of soluble and total silica in ion-exchange resin deionization systems, and the results of this study will be submitted for publication in the near future.

Use of the Orcinol - Sulphuric Acid Reaction in the Positive Identification of Certain Monosaccharides from a Salivary Mucoid

AN approximate identification of sugars separated from hydrolysates of biological material can usually be made by paper chromatography. Positive identification is usually achieved by the measurement of some specific physical property such as optical rotation, or the preparation of derivatives possessing characteristic melting points. It frequently happens that sugars separated from hydrolysates are present in insufficient amounts to enable such methods of identification to be used.

The modified orcinol – sulphuric acid reaction described by Bruckner[1] is eminently suitable for the identification of small amounts of various hexose which give characteristic absorption spectra readil distinguishable from one another. The differen aldopentoses exhibit the same absorption curv which, however, is different from those of th individual hexoses. As little as 0·1 mgm. of th sugar is necessary to obtain a satisfactory absorptio curve.

In the course of our investigations into the composition of mucoids occurring in human saliva, fraction was obtained which was thought to b identical with the 'blood group A substance' describe by Aminoff, Morgan and Watkins[2]. Less tha 100 mgm. of the substance was hydrolysed by refluxing with water in the presence of 1 gm. of 'Amberlit *IR*120' ion-exchange resin at 100° C. for 16 hr. Th resin was filtered off and washed with water. Th combined filtrate and washings were evaporated t dryness *in vacuo* and the residue taken up in 2 ml of water.

One-dimensional chromatograms were run o Whatman No. 1 paper in methyl ethyl ketone/aceti acid/water (6 : 1 : 1), a very rapidly running solvent introduced in this laboratory (Leaver, A. G., an Irwin, M., unpublished work). Two of these gave R_F values approximating to those found for galactose and fucose. When the hydrolysate was again run with spots of these two sugars run adjacently, the tentative identification was confirmed.

The total hydrolysate was applied to three wider strips of the very thick paper Whatman No. 3 *MM*, application being in the 'ribbon' form across the width of each paper. Development was continued for 18 hr., after which the chromatograms were dried, narrow strips cut from each edge and sprayed with aniline hydrogen phthalate. The areas corresponding to the two principal bands obtained were cut out of the main strips and eluted with distilled water. The two eluates were evaporated to dryness *in vacuo*, the solids being weighed and taken up in distilled water to give a concentration of 0·1 mgm. per ml. Both solutions were then treated with orcinol and sulphuric acid, according to the method of Bruckner[1], absorption curves being measured on the 'Unicam' S.P.600 spectrophotometer. The first solution gave the typical absorption curve for galactose, whereas the latter exhibited the highly characteristic spectrum of fucose, which shows maxima at 390 mμ and 500 mμ and is totally different from all other spectra examined (Bruckner, private communication).

Thus galactose and fucose were identified as neutral sugars present in the hydrolysate of the salivary mucoid. It is of interest that Aminoff, Morgan and Watkins[2] found these two sugars in hydrolysates of human 'blood group A substance'.

Use of the orcinol – sulphuric acid reaction for the positive identification of monosaccharides affords a rapid and simple way of making definite confirmation of results obtained by paper chromatography.

We are indebted to Dr. J. Bruckner for his valuable assistance and for making available the unpublished absorption curve for fucose.

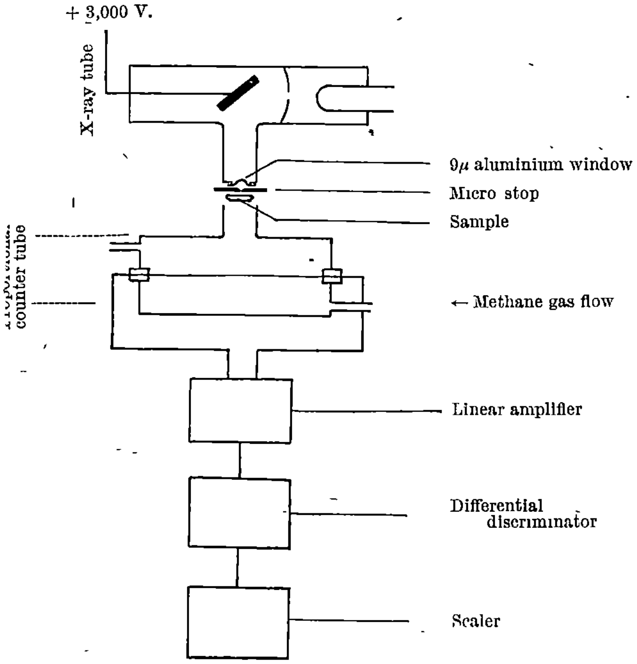
X-Ray Mass Determination in Cells by Scanning

In 1949–50 Engström and Lindstrom published a ethod for determining the cell mass by means of sorption measurements in soft X-radiation. In e wave-length range 6–12 A., the absorption of e X-radiation is proportional to the mass of carbon, trogen and oxygen substances. The cells are photo-aphed together with a reference system in which e absorption – wave-length relationship is the me. The photographic emulsion and process are the ain limit to accuracy and resolving power.

The photographic process can be evaded by anning the section of the cell with a very thin pencil f X-rays, and then measuring the transmission irect. The possibilities of obtaining a measurable nount of X-radiation through a small stop of 1·8μ as first been examined. The wave-lengths must be ithin the limits 6–12 A., and to prevent getting too eat a geometrical unsharpness the pencil of rays ust be almost parallel.

A sealed-off X-ray tube has been constructed hich has a thin window through which the rays ass. The window is of aluminium foil 9μ thick, hich at the same time serves as a filter. The diameter f the focus is 1·5 mm. and the focus-window distance 70 mm. The anode voltage is 3 kV. and the anode urrent 1 m.amp. A gold micro-stop is placed nmediately in front of the window. The rays pass hrough the stop and enter a windowless proportional ounter through which methane is flowing.

The possibility of obtaining measurable quantities f rays through the micro-stop is a problem of ntensity; but it is further complicated by the atural radiation giving a background, the irregular ariations of which can be expected to be greater han the radiation passing through the micro-stop. his problem has been solved in the following way. he height of impulses from the proportional tube epends on the energy of the radiation. The soft, ow-energy radiation which is used here gives very much smaller impulses than the high-energy natural radiation. The high impulses are blocked in a differential discriminator, and only impulses below a certain height reach the impulse counter. Consequently, the disturbing background becomes insignificant. By using this form of X-ray tube and these conditions of operation (Fig. 1), a micro-stop with a diameter of 1·3μ resulted in a mean of 145 impulses/min. being obtained; the background was found to be 15 impulses/min. Quite measurable quantities were thus passing the stop.



Proportional tubes in connexion with the differential discriminator, however, give still another possibility. Impulses below a certain level can also be excluded, and thus only impulses between two levels will be counted. If these levels are set close to each other, it will be possible to measure within a very narrow range of wave-lengths. This means that absorption measurements in cells of various substances can be carried out at their maximum absorption. Further quantitative examination of the chemical components in the cells should thus be possible.

Preliminary investigations have shown that mass determination in cells is possible by scanning with X-rays. Further investigations will be published later on.

Some New Stereochemical Arrangements of Divalent Palladium and Platinum

The usual stereochemistry of divalent palladium and platinum is that of a square-planar arrangement, associated with $(n-1)dnsnp^2$ bonding. A number of structures of this type have been reported[1]. The stereochemistry of square complexes has been discussed in considerable detail by Mellor[2]. With the exception of a few compounds such as the pyrromethene[3] and triaminotrimethylamine[4] complexes, where the bonds must be forced out of a plane, the four bonds to a bivalent platinum atom are invariably planar.

A few compounds have been reported in which the divalent platinum atom has been said to be six-covalent. For example, *bis*-(acetonitrile) tetrammine platinous chloride, $[Pt(NH_3)_4(CH_3CN)_2]Cl_2$, has been prepared in what are claimed to be *cis*- and *trans*-forms[5]. An octahedral arrangement has also been suggested for the *bis*(α,β,γ-triaminopropane) platinous ion[6]. The evidence for the proposed octahedral arrangements is, however, purely chemical.

While investigating recently the complexes of the chelate group *o*-phenylene*bis*(dimethylarsine) (denoted by diarsine) the reaction

$$[M(\text{diarsine})_2]^{++} + X^- \rightarrow [M(\text{diarsine})_2X]^+$$

where X = Cl, Br and I, and M = Pd and Ni, was observed to occur in non-aqueous ionizing solvents such as nitrobenzene, and complexes of the general formula $[M(\text{diarsine})_2X]^+ClO_4^-$ (M = Pd and Ni) have been isolated from acetone solutions[7]. These metals apparently exist as five-covalent ions $[M(\text{diarsine})_2X]^+$ in nitrobenzene solution[7], for the perchlorates function as uni-univalent electrolytes in this solvent. It is to be expected that compounds of the type $[M(\text{diarsine})_2X]^+\text{ClO}_4$ would involve a five-covalent metal ion in the solid state. Special interest is attached to the structure of the series $M(\text{diarsine})_2\text{I}_2$, where $M = \text{Ni}^{\text{II}}$, Pd^{II} and Pt^{II}. These iodides also behave as uni-univalent electrolytes in nitrobenzene solution, presumably forming the ions $[M(\text{diarsine})_2\text{I}]^+$ and I^-, bearing in mind that a molecule of the solvent may be co-ordinated to the cation, thus making the metal six-covalent. The structure of these di-iodides has now been investigated to determine if five- or six-covalency occurs in the solid state.

Single crystals, from nitrobenzene, of the above platinum and palladium compounds have been examined in detail using the Buerger precession camera and molybdenum $K\alpha_{1,2}$ radiation. Apart from small visual variations in spot intensities, the reciprocal lattice nets are identical. The space group is $P2_1/c$ and the unit cell has the dimensions: $a = 9 \cdot 68$ A.; $b = 9 \cdot 27$ A.; $c = 17 \cdot 27$ A.; $\beta = 114° 30'$. It contains two molecules, which must therefore be at centres of symmetry. A satisfactory trial model was obtained using $h0l$ and $0kl$ Patterson maps, and the isomorphous replacement method, using the nickel, platinum and palladium complexes, agreed with these results. The refinement of atomic co-ordinates has proceeded using successive $\{|F(\text{obs.})| - |F(\text{calc.})|\}$ difference syntheses computed along the a- and b-axes. The reliability indexes

$$R = \frac{\Sigma\{|F(\text{obs.})| - |F(\text{calc.})|\}}{\Sigma|F(\text{obs.})|}$$ at present have

the values $R(h0l) = 0 \cdot 13$ and $R(0kl) = 0 \cdot 14$. These values of R include contributions from carbon atoms as well as the heavy palladium, arsenic and iodine atoms. The light carbon atoms showed up quite well despite the presence of the heavier metal and arsenic atoms.

The structure consists of discrete molecules of $M(\text{diarsine})_2\text{I}_2$. The central atom is surrounded by four arsenic atoms in a square plane and at distances of approximately $2 \cdot 38$ A. The two iodine atoms complete a distorted octahedral arrangement with elongated metal iodine bonds of $3 \cdot 52$ A. The calculated Pd—I bond distance in square palladium complexes is only $2 \cdot 65$ A. These preliminary results are in complete accord with bond-lengths expected from the crystal (ligand) field theory. The palladium (II) atom in an octahedral $\text{Pd}(\text{diarsine})_2\text{I}_2$ molecule has eight non-bonding $4d$ electrons. Six of these form a symmetrical closed sub-shell of d_ε orbitals, whereas the remaining two are almost certainly in a $4d_{z^2}$ orbital. The vacant $4d_{(x^2-y^2)}$ orbital points in the direction of the four arsenic atoms and, together with a $5s$ and two $5p$ orbitals, forms four square $4d_{(x^2-y^2)}5s5p^2$ bonds. Pointing along the axis of the two Pd—I bonds is the filled $4d_{z^2}$ orbital, which must exert a strong repulsion upon the two iodine atoms, leading to a considerable increase in bond-lengths. The two iodine atoms might be conveniently regarded as bound by linear hybrid $5p5d$ bonds—an interpretation in accord with the length of the bonds, with ligand field-theory, and with their covalent character.

Compounds of the formula $[M(\text{diarsine})_2X]\text{ClO}_4$, where $M = \text{Pd}, \text{Ni}$, and $X = \text{I}, \text{Cl}$, also form an isomorphous series. The unit cells are body-centred tetragonal and have the dimensions $a = 13 \cdot 33$ A.; $c = 32 \cdot 44$ A. There are eight molecules per cell. The space group is probably $I4_1$. Systematic absences occur when $h + k + l = 2n + 1$ and $001 \neq 4n$.

The structures of these compounds are at presen being examined with the view of determining the presence or otherwise of an asymmetrical five covalent ion in these non-centric cells. A more detailed account of these investigations will b reported in due course.

Cation-Exchange Properties of Zirconium (IV) – Tungsten (VI) Precipitates

IN an investigation of adsorptive properties o inorganic materials, precipitates of tungstate brough down by addition of zirconium (IV) solutions wer found to have cation-exchange properties. Th adsorbent may be prepared by mixing a solution of zirconium oxychloride with a large excess o sodium tungstate solution (adjusted to pH c. 1· with hydrochloric acid). The precipitate (mole ratio tungsten/zirconium of about 3/1) is dried at 25 without washing, ground and screened. The conditions of preparation are not critical, so long as the acidity is not too high. Drying the precipitates for 24 hr. at temperatures above 80° C. sharply decreases both uptake of cations and the values o distribution coefficients D (amount adsorbed per kgm. adsorber/amount per litre of solution); at 150° C. the exchange properties of the solid are essentially destroyed.

Although cations in general can apparently be adsorbed on and eluted from the materials in characteristic cation-exchange manner, most work so far has concerned the alkali metals. For these, adsorption is rapid and reversible, essential equilibrium being attained in a matter of minutes. Under some conditions, at least, the materials show essentially idea ion-exchange behaviour. Thus, in adsorption o tracer cæsium from ammonium chloride solutions, a plot of log D versus log M ammonium chloride gave a straight line of slope minus one in the range studied ($0 \cdot 1$–1 M ammonium chloride). Apparent capacities are relatively high ($0 \cdot 5$ mole cæsium uptake per kgm from $0 \cdot 1$ M cæsium chloride) and selectivities appear good. Thus, distribution coefficients D for cæsium and rubidium were 65 and 21 respectively, in $0 \cdot 1$ M ammonium chloride, and similarly large ratios of D were found for the other alkali metals.

These results suggested that the materials could be used for separations with small columns. As an example, separation of the elements sodium to cæsium on material dried at room temperature is given in Fig. 1; conditions are summarized in the figure.

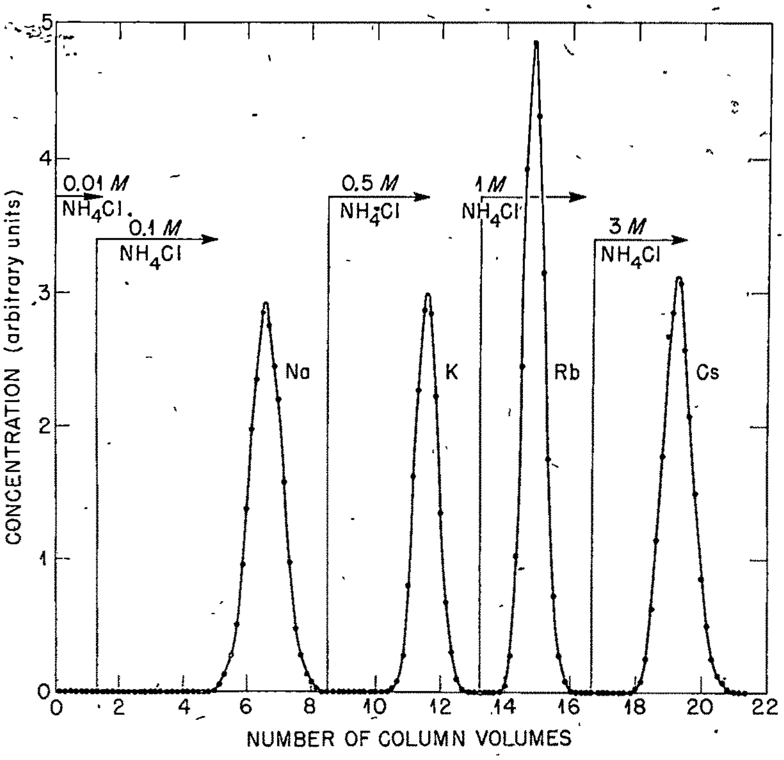

Fig. 1. Zirconium tungstate, 25° C.; column, 11·3 cm. × 0·13 cm.^{2}; flow-rate, 1 cm./min.

While Fig. 1 represents separations of alkali metal tracers, similar separations can be achieved at macro concentrations.

This work was carried out for the U.S. Atomic Energy Commission at the Oak Ridge National Laboratory.

Composition of Egg Phospholipids

THE fatty-acid composition of egg lecithin prepared by the cadmium chloride method has been determined by Riemenschneider *et al.*[1] and of total egg phospholipids by Shorland[2]. Their results agree in finding about 30 per cent of C_{16}, 55 per cent of C_{18} and 15 per cent of C_{20} and C_{22} acids; approximately 39 and 45 per cent, respectively, of the total acids were saturated.

It has been known for some years that the fatty acids split off from lecithin by the phospholipase *A* of snake venom are unsaturated, and more recently it has been proved that the enzyme removes these acids from the α′-position. Hanahan[3] has further shown that the fatty acids of the liver lecithins from various animals are not distributed at random between the two positions available, but that the α′-position is occupied by unsaturated acids only and the β-position exclusively by saturated. The same structure was found in egg lecithin (prepared by an alumina column method), where, moreover, the constituent acids were found to be entirely C_{18}[4]. This permitted the preparation of pure L-α-distearoyl lecithin by the hydrogenation of the natural material and then, by hydrolysis with lecithinase *A* or *C*, of pure L-α-monostearoyl lecithin[4] and of αβ-distearin[5].

Our work, however, suggests that the composition of egg lecithin is appreciably more complicated than that found by Hanahan for his alumina-column preparations.

In the first place, lysolecithins were prepared either by the action of snake venom on egg yolk followed by separation of the resulting lysophospholipids on a silica column, or by hydrolysis with venom of lecithins prepared on a silica column. In both cases they were found to possess a residual unsaturation of about 0·15 double bond per molecule, indicating the presence of a small proportion of lecithins containing two unsaturated residues in the molecule. This is in agreement with a failure to find more than 45 per cent of saturated acids in the total acids of egg lecithin.

Secondly, the fatty-acids recovered from lysolecithin (which had been prepared by the action of venom on the intact yolk and represented 90 per cent of the original lecithin) have been examined, after hydrogenation, by partition chromatography according to Nijkamp[6] and found to consist of 33 per cent stearic and 67 per cent palmitic acid. This corresponds to a content of 33 per cent C_{16} acids in the egg lecithin, a figure similar to that found by the earlier workers.

Thirdly, acids with an average unsaturation of 5 (unconjugated) double bonds per molecule have been recovered from the α′-position of highly unsaturated lecithin fractions obtained from silica columns[7], and spectrophotometric examination after alkali isomerization has confirmed the presence of hexaene and tetraene acids. After hydrogenation the presence of C_{22} and C_{20} acids was demonstrated by the partition chromatogram.

It would appear on the basis of these results that not more than one-third, and possibly considerably less, of the lecithin of the egg yolks examined by us can have the simple di-C_{18} structure found by Hanahan for his alumina-column preparations, and that hydrogenation of lecithin obtained from eggs cannot therefore be relied upon to yield an individual distearoyl lecithin or its hydrolysis products by enzymic treatments.

It is well established that the fatty-acid composition of egg phospholipids is markedly dependent upon that of the dietary fats; but it seems unlikely that such a factor would account for the complete absence of C_{16}, C_{20} and C_{22} acids in the lecithin described by Hanahan.

Examination of the lysophosphatidylethanolamine obtained from venom-treated yolk has shown that its constituent acids also have a small unsaturation of the same order as that of the lysolecithins. In this case the hydrogenated acids consisted of 47 per cent stearic and 53 per cent palmitic. Assuming that the action of the venom phospholipase is at the α′-position, as in the case of the lecithinase *A*, it may be concluded that the phosphatidylethanolamine of egg yolk has the same type of fatty-acid distribution as the lecithin.

A detailed account of this work, which forms part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research, will be published elsewhere.

Characterization of an Enzyme reducing Pyrroline-5-Carboxylate to Proline

SEVERAL lines of evidence serve to establish glutamic-γ-semialdehyde as the key intermediate in the pathway of the biosynthesis of proline from either glutamic acid or ornithine[1,2]. Since glutamic-γ-semialdehyde spontaneously cyclizes nearly completely to Δ^1-pyrroline-5-carboxylic acid[2], hydrogenation of the latter becomes a key reaction in the biogenesis of proline.

An enzyme catalysing this reaction has been observed in extracts of mycelial pods of *N. crassa* and named pyrroline-5-carboxylate reductase[3]. Extracts of rat liver mitochondria have been shown to convert glutamic semialdehyde to proline; but efforts to increase the activity failed[4].

We have determined that pyrroline-5-carboxylate reductase occurs in the soluble proteins of liver. The enzyme has now been partially purified by ammonium sulphate fractionation and the hydrogen donor has been shown to be reduced diphosphopyridine nucleotide. The enzyme has also been characterized with respect to a number of its properties.

Assays of the enzyme are carried out by measuring the fall of absorption of reduced diphosphopyridine nucleotide at 340 mμ in the Beckman spectrophotometer as the reduction proceeds (see Table 1).

Table 1

	Experiment	Change in optical density per 10 min.
1.	Pyrroline-5-carboxylate + enzyme (0·8 mgm.) + DPNH	0·300
2.	DPNH + enzyme (no pyrroline-5-carboxylate)	0·01
3.	DPNH + pyrroline-5-carboxylate	0

The enzyme is prepared from rat liver homogenized in a Potter–Elvehjem homogenizer with 1·5 volumes of 0·025 *M* phosphate buffer at *p*H 8 and centrifuged at 100,000 *g* for 30 min. Neutral saturated ammonium sulphate is stirred into the supernatant fluid at 4° to obtain the fraction precipitating between 40 and 60 per cent saturation. This is reprecipitated, dissolved, then reprecipitated and subjected to successive elutions with 50, 45, 40 and 35 per cent saturated ammonium sulphate respectively. The solution resulting from elution with 35 per cent saturated ammonium sulphate is usually most active. This is dialysed for 18 hr. at 4° against four changes of 0·05 *M* phosphate buffer, *p*H 8.

The cuvette for assay contains 3 ml. of 0·05 *M* triethanolamine, 0·04 ml. of pyrroline-5-carboxylate, 0·1 ml. of enzyme solution, containing approximately 1 mgm., and 0·2 ml. reduced diphosphopyridine nucleotide (∼0·5 mgm.). The total mixture is adjusted to *p*H 6·8.

The crude supernatant fluid contains an inhibitor fraction which is eliminated as the enzyme is purified. A doubling of the total enzyme activity is obtained in the first precipitation of the 40–60 per cent saturated ammonium sulphate fraction. This inhibitor seems to be precipitated at less than 40 per cent saturated ammonium sulphate.

A preliminary determination of the properties of pyrroline-5-carboxylate reductase has shown that it is unstable in acid and has an optimum *p*H at 6·8 in 0·05 *M* triethanol amine.

The enzyme is inhibited by *p*-chloromercuribenzoic acid, mercuric and silver ions at a concentration of 10^{-5} *M*. *BAL* (1-hydroxy-2,3-dithiolpropane) protects the enzyme from this inhibition, indicating the participation of an active SH group in the reaction. Ethylenediaminetetraacetic acid does not affect the enzyme activity, but adenosine triphosphate, at a level of 10^{-4} *M*, inhibits the reaction.

Studies are now in progress to characterize still further the properties of the enzyme and the inhibitor fraction.

Effect of Reserpine on Serotonin in Rabbit Serum

IT is generally accepted that the effect of clinical doses of reserpine on the circulation is central in origin and that such doses have no peripheral effect of any significance. It has recently been shown that reserpine and serotonin have similar effects on the central nervous system, and that relatively large doses of reserpine in dogs markedly increase the urinary secretion of a metabolite of serotonin[1]. It has therefore been suggested that certain actions of reserpine are mediated through the liberation of serotonin from the intestine[2].

We have shown that, in rabbits, relatively small doses of reserpine reduce the concentration of serotonin in the serum. In our experiments rabbit serum was tested on the rat œstrous uterus, and compared with known concentrations of 5-hydroxytryptamine creatinine sulphate. The accuracy of this method is about ± 10 per cent. The effect of the serum was presumed to be due to the serotonin content, as histamine does not affect the rat uterus and acetylcholine is not found in serum. As further proof of this presumption, it was shown that similar contractions, produced by the serum, and by

able 1. Effect of Various Intravenous Doses of Reserpine

-hydroxytryptamine, were antagonized to the same xtent by ergot alkaloids.

We have not been able to demonstrate any ntagonism between reserpine and serotonin *in vitro*. ven high concentrations of reserpine (10 μgm./ml.) ave no effect on the sensitivity of the rat uterus to erotonin. Uteri from rats pretreated for several ays with toxic doses of reserpine showed no change sensitivity to serotonin as compared with normal reparations.

Fig. 1 and Table 1 demonstrate some of the results btained after intravenous injection of reserpine. he serum content of serotonin falls rather rapidly; or example, it is reduced to half its original value wo hours after a dose of 1 mgm. reserpine to a abbit.

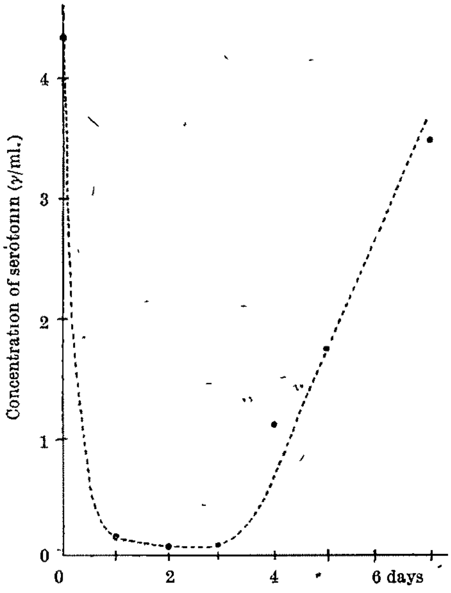

Fig. 1. Effect of three intravenous doses of 0·2 mgm. reserpine (at zero time and on each of the first two days) on the concentration of serotonin in serum. Rabbit weight: 3,350 gm.

We think that this effect can best be explained by a disappearance of serotonin from the platelets, these being the accepted source of the serotonin released during coagulation. The delayed disappearance of serotonin from the serum probably indicates an effect of a metabolite of reserpine rather than a direct effect of reserpine itself.

The possibility of a direct effect of reserpine on the platelets *in vitro* is now under investigation.

Oxidation of Octanoic Acid by Cell-free Bacterial Extracts

Studies with extracts from the anaerobic organism *Clostridium kluyveri* have shown that certain fatty acids are oxidized to acetate by processes similar in essentials to those in mammalian systems[1]; but the mechanisms employed by aerobic bacteria have remained obscure. Thus, although results with whole cells of *Serratia marcescens*[2] did not apparently accord with β-oxidation, it has been shown more recently that extracts from *Pseudomonas fluorescens*[3] catalyse the formation of acetate from decanoate with the uptake of one micromole of oxygen per micromole of substrate. In experiments with cell-free extracts prepared from a vibrio[4], we have now been able to show that octanoic acid is oxidized by molecular oxygen to 2C units; that diphosphopyridine nucleotide, coenzyme A and magnesium ions are co-factors in this process; and that subsequent oxidation is by way of the tricarboxylic acid cycle.

After growth with forced aeration in a mineral-salt medium supplying octanoic acid as sole source of carbon[5], each 10 gm. (wet weight) of cells was crushed in a Hughes press[6] at − 14° C.; and while still frozen, the cells were ground in a mortar to a smooth paste with 10 gm. of alumina and 25 ml. of phosphate buffer. Centrifuging to remove alumina and cell debris gave clear extracts which contained about 18 mgm. protein per ml. and catalysed the oxidation of octanoate (Fig. 1). The rate of oxidation decreased with time, and the volume of oxygen utilized approached that for complete oxidation, namely, 11 moles oxygen per mole octanoate, when fumarate was added: thus four moles oxygen had been utilized in excess of the control after 40 min. and eight moles after 150 min.

The high rate of oxygen uptake in the absence of added substrate was largely abolished by dialysis against water or ethylenediamine tetraacetate, as shown in Fig. 2; and after this treatment, only

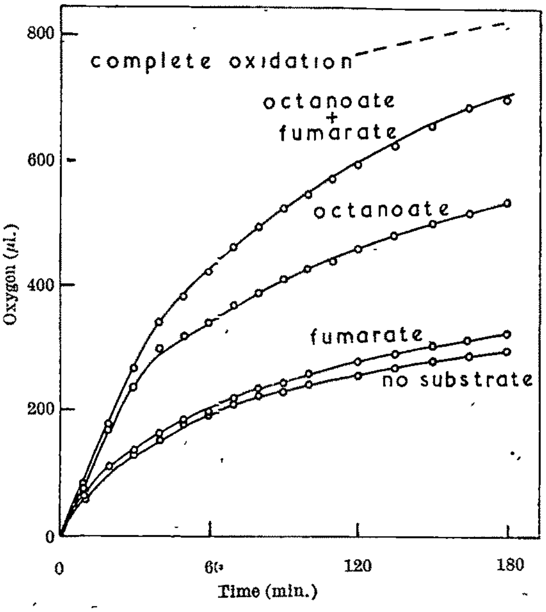

Fig. 1. Aerobic oxidation of octanoic acid by an undialysed extract. 2 μmoles of the substrates indicated were present with 1 ml. of extract in a total volume of 3 ml. Co-factors at concentrations given in Fig. 2 were also present

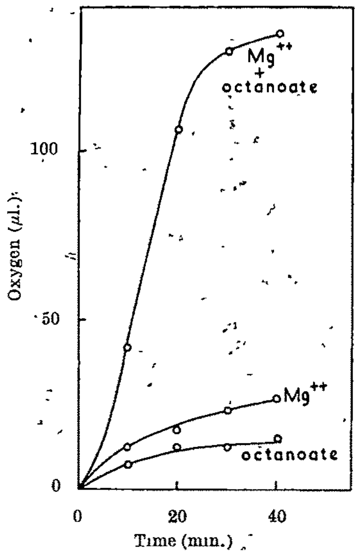

Fig. 2. Oxidation of octanoic acid by an extract dialysed for 3 hr. against ethylenediamine tetraacetate (0·02 *M*; *p*H 7·2). Reaction vessels contained, per 3 ml., 1 ml. of extract, 5 µmoles reduced glutathione, 0·1 µmole coenzyme A and 0·3 µmole diphosphopyridine nucleotide. Additions were as indicated: octanoate (2 µmoles) and magnesium sulphate to a final concentration of $1 \cdot 3 \times 10^{-2}$ *M*

2·5–3 moles oxygen was then utilized when diphosphopyridine nucleotide and magnesium ions were added. In an experiment similar to that of Fig. 2, overnight dialysis against distilled water gave a preparation which oxidized 2 µmoles of octanoate, present in 3 ml. of reaction mixture, at the rate of 60 µl. oxygen per hr. when diphosphopyridine nucleotide was absent, and at 90 µl. oxygen per hr. on addition of 0·3 µmole of diphosphopyridine nucleotide. In these experiments, in addition to $1 \cdot 3 \times 10^{-2}$ *M* magnesium sulphate, 0·1 µmole of coenzyme-A and 5 µmoles of reduced glutathione were also present. Subsequent experiments showed that the latter was not essential; but after treatment of extracts with 'Dowex-1' a stimulation of oxygen utilization by octanoate from 50 µl. per hr. in the absence of added coenzyme-A to 90 µl. per hr. in the presence of 0·1 µmole of coenzyme-A was obtained.

Oxidation of octanoic acid by dialysed extracts in the presence of added co-factors was accompanied by an increase in volatile fatty acid. After deproteinization with metaphosphoric acid, flask contents were distilled in an apparatus and approximately 6 µmoles of volatile acid were obtained from 2 µmoles of octanoate compared with the 8 µmoles of acetate required by the reaction $C_8H_{16}O_2 + 3O_2 \rightarrow 4CH_3COOH$. Further experiments, however, showed that addition of 5 µmoles of acetate caused a marked reduction in rate of oxidation, and it appeared that accumulation of acetate in the reaction mixture might inhibit the breakdown of a small fraction of the octanoate; this was also indicated by total oxygen uptakes rather less than the three molecules required. When volatile acid production was related to oxygen consumed, yields 90 per cent of theoretical were obtained. No keto-acid was detected; and examination of flask contents on extraction with ether, using gas–liquid partition chromatography, revealed acetic acid only.

Previous work has shown that, in the presence of fluoroacetate, this organism accumulates citrate during octanoate oxidation[7]; and cell-free extracts are able to oxidize citrate[8]. When this is considered with the present findings, it appears probable that octanoate is broken down to 2C units which ar then oxidized by the reactions of the tricarboxyl acid cycle. Dialysis probably prevents the operatio of the latter by removal of 4C compounds present i extracts; this observation points to the necessity o a mechanism for 4C replenishment by cells growin at the expense of fatty acids[5]. The tendency of fre acetate to inhibit octanoate breakdown suggests th existence of a regulatory mechanism maintaining balance between the rates of operation of the fatt acid[9] and tricarboxylic acid cycles.

I wish to thank Mr. J. R. L. Walker for his assistance in the determination and identification of acet acid; Mr. T. J. Bowen, who constructed the apparatu for vapour-phase chromatography; Mrs. M. Lee for skilful technical assistance; and the Agricultural Research Council for a grant.

Bacterial Variation to Sensitivity: an Example of Individuality in Micro-organism

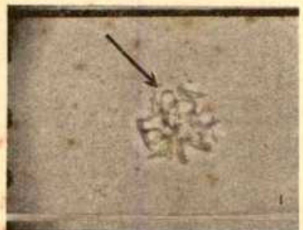
IT is now a commonplace that, in culture, resistan organisms may be already present before there ha been any contact between them and an antibiotic[1] I demonstrated[1a] that this was true even in youn cultures derived from single cells.

While it has been relatively easy to demonstrat that there is a regular distribution of resistanc through these populations, there has not so far bee any published evidence that increased sensitivity wa similarly distributed. There is evidence of the production of true-breeding mutants which are man times more sensitive than the parent strain[2]; bu this is a different order of phenomenon from th graduated series of variants here being considered.

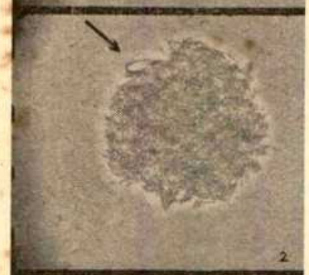
If phase-contrast microscopy be supplemented b time-lapse ciné-micrography, it is possible to demonstrate that organisms more sensitive than the paren cell are produced in micro-colonies in 'sub-inhibitory concentrations of antibiotic. These cells are no normally noticed since they are eliminated by lysis leaving nothing to indicate that selection has bee at work. The alternative method, which involve the testing of individual organisms by transferrin them singly to antibiotic agar or other unfavourabl environment, is so laborious that only a few generations can be studied[3].

The results shown by ciné films have been s instructive that it seems justifiable to report a typica preliminary finding here.

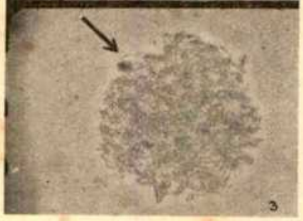
Fig. 1 shows a young colony derived from a singl cell and growing on one-fifth of the normal inhibitor dose for the strain. Of the individual cells present only one, marked with an arrow, is sensitive at thi level of penicillin. Fig. 2 is of the same colon 230 min. later; it shows that this cell alone has faile to divide. Fig. 3 is the next frame in the film, onl



1



2

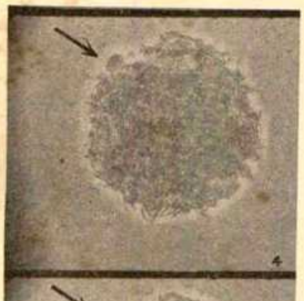


3

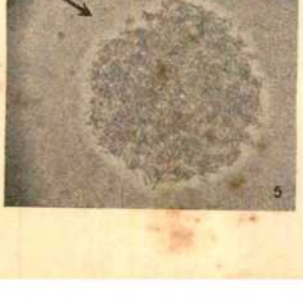
20 sec. later, and records the bursting of this cell. Its contents flow out and are visible for 23 min., but then disappear between one frame and the next (Figs. 4 and 5), leaving nothing that can be resolved by the light microscope.

At higher concentrations of antibiotic, this individuality of reaction in cells derived from a single parent can also be seen. In a field of three or four organisms, all inhibited for division but able to grow in size, it is usual to find at least one that is obviously more sensitive and is destroyed while its fellows survive to give rise to fresh generations many hours later. Some sensitive cells appear in the cultures no matter how often the strain has been exposed to the antibiotic.

I therefore feel justified in advancing the hypothesis that, whenever a microbe divides, the daughter cells will differ from one another and from the parent cell from which they came. The so-called 'clone' of organisms is a population of separate individuals normally distributed for any measurable character and subjected to continuous re-selection by an unfavourable environment. Selected populations are not soon permanently altered, as they would be by mutation proper, but will show similar reactions at each fresh contact with the unfavourable environment.



4



5

In reviewing the records made during the eight years in which phase-contrast microscopy has been available, I have never observed anything that might throw doubt on this hypothesis. Photographs and films published by others also support this view. Vadasz and Juhasz[4] although primarily interested in the origin of resistance, show pictures of *Salmonella enteritidis* similar to ours with *Proteus vulgaris*. Further evidence is available from such divers fields as Lwoff and Gutmann's[5] studies on phage production in *Megatherium* and Crawley and Jevons's[6] recent publication on the synthesis of carbohydrate by streptococci.

The supervision of the ciné-micrographic technique used was in the hands of Dr. Peter N. Cardew, of the Photographic Department, St. Mary's Hospital Medical School, and the apparatus was designed and largely built by him.

Free Amino-acid Content of the Lymph

We have been studying the free amino-acids of the blood and urine by quantitative paper chromatography[1]. This method also offered the possibility of extending our researches on lymph and of comparing the free amino-acid content of lymph and blood obtained from different areas.

Our experiments were carried out on six dogs. Under 'evipan'-anæsthesia we isolated the thoracic duct, the cervical lymph ducts and the lymph duct running along the vena portæ, and gathered lymph through cannulæ. At the same time, we drew blood from the jugular vein and from the portal vein too.

In these samples the free amino-acids were determined in the following way. The deproteinization of the blood or lymph was carried out by alcoholic precipitation and the removal of lipids by shaking with ether. Desalting was done by the method of Consden and Gordon. The amino-acids were separated by two-dimensional ascending paper chromatography in a phenol/*n*-propanol/water, or in some cases in a phenol/*n*-butanol/acetic acid/water solvent system. The principle of the method of determination was to make the amino-acids visible by spraying the paper with diluted ninhydrin solution, removing the ammonia-like impurities of the paper by spraying it with alcoholic potash solution. The spots were cut out and their amino-acid content determined by our previously published method[2] with recent modifications (unpublished). The ninhydrin reagent used in

this method is similar to that of Moore and Stein[3]. The determination of proline was made by our modification of Schweet's method[4]. In accordance with Stein and Moore's results[5] we also observed that glutamine may be slightly decomposed during the procedure. To minimize this error, the standard glutamine solution was submitted to the same procedure before determination. The relative limit of our method is about ± 10 per cent. The results are given in Table 1.

Summing up our observations: (1) the amino-acid pattern of lymph is similar to that of the serum; (2) in some experiments we have found striking differences in the concentration of individual amino-acids of different samples, certainly exceeding the error of our method (see detailed publication in *Acta Med. Hung.*, in the press), but systematic, unidirectional differences were not to be found; (3) the amino-acid in the highest concentration in all materials was glutamine, that in lowest concentration aspartic acid.

The concentration of individual amino-acids in the systemic blood and portal vein in dogs was investigated recently by Denton and Elvehjem[6]. Comparing our results with theirs, the values for arginine, histidine, leucine, phenylalanine, threonine, tryptophan and valine correspond, despite the diversity of the methods. Our determinations of histidine, phenylalanine, tryptophan and tyrosine agree also with the results of Hier and Bergeim[7]. In disagreement with the available data on dog plasma, the concentration of lysine is comparatively low. This may be connected with the loss of this amino-acid arising from the method of preparation (for example, desalting). This problem has not been dealt with in detail.

Our investigations will be published fully in *Acta Med. Hung.*

Reciprocal Egg Transplantations to study the Embryo–Uterine Relationship in Heat-induced Failure of Pregnancy in Rabbits

PREGNANCY in rats[1], mice[2] and ewes[3] is adversely affected by high ambient temperature. Experiments described here were undertaken to see if rabbits, too fall in this category; and if so, whether the heat acts directly on the embryos, the uterus, or both.

In the first experiment, the course of pregnancy was studied in eight rabbits, following continuous exposure to high temperature for six days following copulation. The heat-treatment was carried out in a thermostatically controlled chamber. The average air temperature was 95·9° F. dry-bulb and 78·8° F. wet-bulb. This raised the rectal temperature of the rabbits from an average of 102·5° F. in the normal environment to 105·1° F. during the six-day period of heat-treatment. Before and after heat-treatment the rabbits were kept in the normal environment. The course of pregnancy was followed by laparotomy between the tenth and fifteenth day post-coitum, by abdominal palpation of conceptuses, and by autopsy in cases of pregnancy interruption. Prenatal losses were estimated by the method of Allen, Brambell and Mills[4]. Entire litters were resorbed in seven of the eight heat-treated rabbits, and a partial resorption occurred in the eighth doe, in which two out of five conceptuses, observed at laparotomy, were carried to term. Observation of corpora lutea, implantations and resorptions of embryos in the eight heat-treated rabbits revealed that, on the basis of ovulations, prenatal losses were 96·2 per cent, of which 75·6 per cent occurred by way of resorptions following implantation. Pre-implantation losses were unaffected. Thus a continuous exposure of rabbits to high air-temperature during the pre-implantation period of pregnancy (six days post-coitum) resulted in severe prenatal mortality through resorption of embryos, following normal implantation. The resorptions occurred mainly between the tenth and fifteenth day of pregnancy and to a smaller extent after the twenty-first day. Control experiments showed that the interruption of pregnancy was unrelated to a lowered food intake during heat-treatment, or to laparotomy.

In the second experiment the technique of egg transplantation was employed to study the embryo–uterine relationship in this interruption of pregnancy. Normally, transplantation of six-day rabbit eggs would involve incision of the uterus of a pseudo-pregnant recipient for transfer of eggs[5]. However, in the transplantations reported here uterine incision was avoided by transferring eggs to the uterus via the cervix through an incision in the vaginal canal of laparotomized recipient females. Pyometra, usually encountered following transplants in the presence of active corpora lutea in rabbits[6], was obviated by the local use of aureomycin and intramuscular injections of penicillin. Using this technique, thirty-two six-day eggs from unheated donor rabbits were transferred to the uteri of five unheated six-day pseudopregnant recipients. In all, twelve normal young were born to four of five recipients, representing a normal development to term of 37·5 per cent of transferred blastocysts. These transplantations, in which both donors and recipients were kept in the normal environment, formed the controls for experiments three and four, involving heat-treatment of either donors or recipients.

In the third experiment, thirteen donor rabbits were subjected to heat-treatment for six days (144 hr.) following copulation with fertile bucks. At the end of heat-treatment they were killed and seventy-four blastocysts were collected, which represented 72·5 per cent of 102 ovulations (on the basis of corpora lutea). This figure compares favourably with a 74·4 per cent recovery of six-day blastocysts from normal unheated donors[7]. Forty-two six-day eggs from the heated donors were transferred to the uteri of eight unheated six-day pseudopregnant recipients. Seven of the eight recipients produced fifteen normal young, representing a development to term of 35·7 per cent of eggs transplanted against 37·5 per cent in control transplantations. Thus, embryos recovered from donors heat-treated for a period of six days post-coitum undergo normal development to term in the uteri of unheated pseudopregnant recipients. This shows that embryos up to six days of age are unaffected by heat—a finding which is substantiated by the fact that a similar number of blastocysts may be recovered at six days from either heated or unheated donors.

In the fourth experiment, all donors were kept in the normal environment, but recipient rabbits were subjected to continuous heat-treatment for 144 hr. following mating to vasectomized bucks. Sixty-six six-day blastocysts from unheated donors were transferred to the uteri of nine heat-treated six-day pseudopregnant recipients. Recipients were left in the normal environment following transplantation, and pregnancy was diagnosed by abdominal palpation at regular intervals. Recipients were autopsied if and when their pregnancies were diagnosed as regressing. Implantation of transferred embryos occurred in all nine heat-treated recipients; but at stages subsequent to implantation entire litters were resorbed in eight of them. In these eight recipients, resorption of embryos occurred mainly between the twelfth and fourteenth day post-coitum, and to a smaller extent after the twentieth day. The ninth doe, which was killed on the tenth day post-coitum, appeared to have normal conceptuses at that time; but these perhaps would have resorbed had the animal not been autopsied prematurely. From this experiment it is clear that when six-day blastocysts from unheated donors are transplanted to heat-treated pseudopregnant recipients, embryos become implanted, but most of them afterwards undergo resorption. This shows that continuous heat-treatment for six days renders the uterus unsuitable for the normal development of embryos.

These experiments have shown that normal pregnancy in the rabbit was interrupted by high temperature during the first six days of gestation. This was caused by heat acting adversely on the maternal tissues rather than directly on the embryos themselves.

My thanks are due to the Government of the Commonwealth of Australia for the award of a junior fellowship under the Technical Co-operation Scheme of the Colombo Plan enabling me to carry out this work; to the Government of India for sponsoring my application; to the University of Queensland for extending research facilities; to Dr. N. T. M. Yeates, of the Commonwealth Scientific and Industrial Research Organization of Australia, for his continued guidance; and to Prof. W. V. Macfarlane and the staff of the Physiology School, University of Queensland, for their help.

Determination of Sex in Early Human Embryos

The presence of sex-chromatin in cell nuclei is being noted in an ever-increasing number of tissues from human and animal females[1-9]. Popular interest was roused recently by a report in *Nature*[10] describing a method of antenatal sex determination. The method depends on the presence or absence of sex-chromatin in desquamated cells isolated from amniotic fluid.

An examination has now been carried out of the human embryos and fœtuses in this Department. The collection comprised twenty-two male and twelve female fœtuses, ranging in size from 18 to 150 mm. crown-rump length. All the specimens have been stained with hæmatoxylin and eosin. Most of the specimens were sufficiently well fixed and stained for nuclear details to be observable.

The presence of a dark-staining plano-convex particle in contact with the nuclear membrane of vesicular, 'open-faced' nuclei was taken as indicating the presence of sex-chromatin. Shrunken, pyknotic, too densely stained nuclei, or those overlapped by other structures, were unsuitable for study. Using these criteria, the presence or absence of sex-chromatin corresponded in each case with the sex of the fœtus as determined by the histological appearances of the gonads. Sex-chromatin particles were identified in 30–50 per cent of nuclei examined in the tissues of the female fœtuses. Although sex-chromatin could be identified in many tissues, the nuclei most suitable for examination were found in the liver, suprarenals mesonephric tubules, surface epithelium, cardiac muscle, undifferentiated mesenchyme, notochord and cartilage. However, the latter was often insufficiently well preserved to be reliable. It should also be noted that the morphological sex differences described above are also demonstrable in both layers of the trophoblast.

In male fœtuses doubtful nuclei were occasionally encountered but they never exceeded 10 per cent of the nuclei counted. A closer examination of these nuclei usually revealed a degree of irregularity of the nuclear membrane. As there appears to be a concurrence between the incidence of sex-chromatin in fœtal cells and the presence of ovarian characters in the gonad, young embryos in which the gonad had not yet differentiated into a testis or ovary were examined. Thirteen embryos were suitable for this examination, and six were found to possess a sufficient number of nuclei containing sex-chromatin to warrant their classification as females. The youngest specimen showing this feature was a 1·7 mm. pre-somite embryo. In addition, the syncytiotrophoblast cells of an implanting blastocyst were seen to contain the sex-chromatin particles, although the cells of the embryonic disk and the cytotrophoblast were not suitable for the test.

These results are presented as they appear to be significant, and the method may prove useful in the determination of sex in early embryos. It is realized, however, that more specimens will have to be examined and more experience gained before the test can be said to be entirely reliable.

Effect of Electric Shock and Cardiazol Shock on Morphine Tolerance

During my investigation of the tolerance for morphine and codeine using 'coughing dogs'[1], I noted that acquired tolerance for these drugs by which their antitussive effects were completely lost was reduced or eliminated by an electric shock or a cardiazol shock. Morphine (2–6 mgm./kgm.) given intravenously completely depressed coughing for 1–6 hr. in such dogs on the first day of administration. By continued daily application of the drug, the dogs acquired tolerance in five to ten days; but the same drug failed to depress coughing afterwards. Similar tolerance for codeine developed in eight to fourteen days. The dogs thus made tolerant for morphine or codeine were subjected to an electric shock (a.c. 90–100 V., 2 sec.) or cardiazol shock (30–50 mgm./kgm.). On the following day, each antitussive drug was one-fourth to three-fourths as potent, or in a few cases, quite as potent, as on the first day of administration, indicating that the shock had reduced or eliminated the tolerance.

The effect of the first shock persisted for three to four days, after which another shock was required to eliminate the redeveloped tolerance. Neither of the shock therapies affected the antitussive action of morphine in any non-tolerant dogs, and the combined application of morphine and electric shock for many consecutive days failed to prevent the animals from acquiring tolerance for morphine. Excepting the rare cases, the effect of an electric shock or cardiazol shock was proportional to the severity of the resulting convulsion and excitement.

From the following observations it is presumed that the effect of shock may in part be ascribed to the increased permeability of cerebral blood vessels and brain tissue. (1) Intravenously administered trypan blue, which left brain and spinal tissue unstained in normal dogs[2], stained brain tissue blue when accompanied by an electric shock (however, the nerve cells contained none of the dyestuff). (2) Hyaluronidase (10,000 v.r.u./kgm.) mixed with morphine reduced tolerance without causing convulsions, though the effect was far weaker than that of an electric shock. Brain tissue was also stained with trypan blue during hypertension produced with adrenaline; but the hypertension itself did not reduce the tolerance for morphine.

These facts suggest that the staining of brain tissue with trypan blue after application of an electric shock is mainly attributable to enhanced permeability of cerebral blood vessels due to the hypertension induced by convulsion, and that the effect of the shock on morphine tolerance may be based on its action of enhancing the permeability of brain tissue (especially the nerve cells themselves). Possibly the effect of shock therapy on a narcotic addict is in part based on the reduction of drug tolerance described above.

Further investigations have shown that: (1) tolerance can be acquired only when morphine reaches the central nervous system via blood vessels, and not via the cisterna cerebellomedullaris, for the tolerance developed in five to fourteen days by intravenous or intra-arterial injection (common carotid artery), but never developed by daily intracisternal injection for six months; (2) when complete tolerance was obtained by daily intravenous administration of such a dose of morphine that would give much longer duration of antitussive effect than that given intracisternally, the same dose as that administered intracisternally before was given into the cisterna again; however, tolerance did not affect the intracisternal effect, that is, the intracisternal effect was almost equal to that before tolerance had been acquired.

Hair-line Cracks in Low-alloy Steels

The cause of hair-line cracks in low-alloy steels has been debated for many years. The main hypotheses now current can be reduced to the following: the hydrogen-pressure hypothesis and the residual stress hypothesis. It follows from the former that hydrogen alone can induce hair-line cracks to form; and from the latter that, in the absence of residual stress, no hair-line cracks will form even if hydrogen is present.

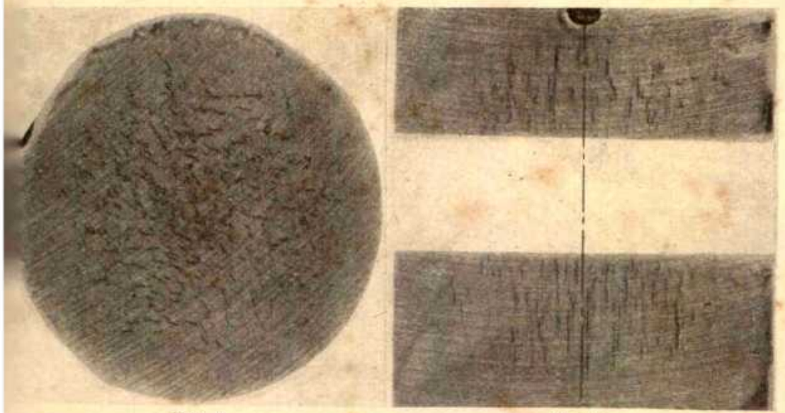

Fig. 1 Fig. 2

(1) Transverse section at mid-length. (2) Longitudinal section. The centre line is vertical. The missing centre portion is where the section shown in Fig. 1 was taken. Magnetic etch. Diameter of the section, 4 in.

Dana, Shortsleeve and Troiano[1] have recently studied the effect of transformations and hydrogen content on the formation of hair-line cracks. One of the conclusions reached was that transformation stresses must be present for cracks to form. Petch[2] also concludes that the hydrogen-pressure hypothesis is not likely to explain hair-line cracking.

We have carried out experiments in which cylinders of steel 4 in. in diameter × 4 in. long have been saturated with hydrogen at 100 atmospheres pressure at subcritical temperatures (between 600° and 650° C.), the specimens afterwards being air-cooled. Under these conditions, no transformation takes place and the residual stress after treatment at 600° C. and air cooling will be small.

By this means, hydrogen contents of between 12 ml. and 14 ml./100 gm. have been obtained in several steels. Plain carbon steels with 0·1 per cent carbon did not contain hair-line cracks after this treatment. With steels of the following composition :

	C	Si	Mn	Ni	Cr	Mo
Steel *A* :	0·28	0·26	0·62	2·76	0·77	0·54 per cent
Steel *B* :	0·30	0·19	0·42	4·22	1·27	0·16 per cent

typical hair-line cracks have been found to form.

An example is shown of steel *A* (Fig. 1), originally oil-quenched and tempered at 630° C. followed by hydrogen treatment at between 570° C. and 620° C. for 20 hr. Supersonic examination showed small hair-line cracks on cooling to room temperature, which gradually increased in size and number with time. The sections shown were obtained 120 hr. after air cooling. The hardness was 280 V.D.H. after treatment. In all cases, supersonic examination showed that the specimens were free from hair-line cracks before the hydrogen treatment.

Houdremont and Schrader[3] have described an experiment in which 2½-in. diameter specimens of a nickel chromium steel of similar composition to steel *B* (Fig. 2) were exposed to hydrogen at 1,000 atmospheres pressure and 550° C. and then either water-quenched or furnace-cooled. Many hair-line cracks were present after water quenching, but only a few in the furnace-cooled specimen. Although about three times the hydrogen content would be present at a temperature compared with the experiments described above, the relatively small size of the specimen would result in much more hydrogen being lost from the centre of the specimen in the slow-cooling treatment than would be the case with the 4-in. cylinders in our experiments.

These experiments indicate that hair-line cracks can form when residual stresses are very low. The local stresses caused by hydrogen pressure are insufficient to crack the softer mild steels, but are sufficient to cause brittle fracture in the nickel steels. Residual stresses due to both transformation and cooling effects would be expected to be additive to the basic hydrogen pressure-induced stresses. In most practical cases the macro residual stresses will be low ; but the micro transformation stresses are likely to be of considerable importance.

We wish to thank the directors of Thos. Firth and John Brown, Ltd., for permission to publish this communication.

Dependence of Snowfall on Temperature

D'Ooge has reported[1] a correlation between amount of snowfall in inches and temperature at the time of snowfall. His data showed that maximum depth of snowfall occurred at a daily mean temperature of − 11° C. ; Bossolasco[2] correlated frequency of occurrence of snowfall with temperature and found maximum occurrence at approximately the same temperature. These observers assumed that the mean daily temperature recorded at the level of observation was a reasonable estimate of the temperature at the level of formation of the snow. From the data presented, conclusions were drawn concerning nucleation of snow crystals.

The dependence observed by D'Ooge was checked by analysing, on a monthly basis, data collected by the Canadian Meteorological Service at Old Glory Mountain (elevation 7,700 ft.) over the period 1947–55. The observed dependence of inches of snowfall on the mean daily temperature is shown in Fig. 1. Assuming that the distributions are due to a real dependence of the amount of snowfall on the temperature at which the snow is forming, Fig. 1 indicates that only during the midwinter months are the temperatures measured at the level of observation likely to be a reasonable estimate of the temperature at the level of formation. The distributions for the remaining months are shifted to higher temperatures, as would be expected when the effect of the annual variation in mean temperature at the ground is taken into account.

It was pointed out to us by members of the Canadian Meteorological Service that these distributions do not necessarily show a true correlation of amount of snowfall on temperature. Other possible explanations exist ; for example, the observed

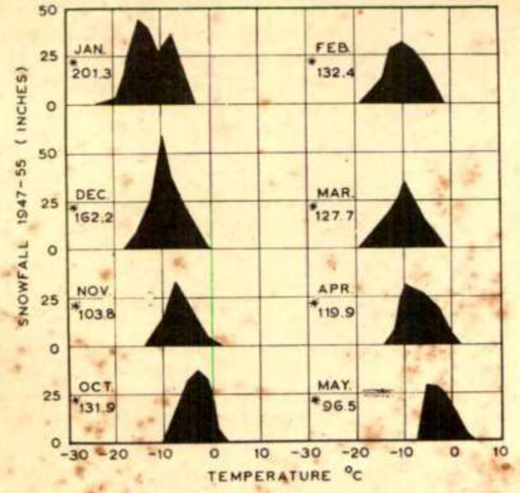

Fig. 1. Dependence of monthly snowfall on temperature at Old Glory Mountain for period 1947–55
• Total snowfall in inches, 1947–55

distribution may be a reflexion of the frequency distribution of the temperatures at the fixed level of observation. Data were available from observations taken at Montreal during the winter of 1951–52 [3] which gave the depth of snowfall and the temperature at the level of formation as estimated from the meteorological records. The distribution obtained from these data is shown in Fig. 2. The area enclosed in the distribution corresponds to 89 in. of the winter total of 124 in. Assuming that air masses in which the snow forms will not produce precipitation until conditions are favourable, Fig. 2 should be a true correlation between amount of snowfall and the temperature at the level of formation. From this distribution it is seen that the greatest amount of snow is likely to come from cloud between − 10° C. and − 20° C. One interesting feature of the Montreal observations was that the majority of snow crystals were irregular assemblages of columns and plates[4]. The distribution in inches for the snowfalls observed was: 59·0 in., irregular crystals (usually associated with frontal storms); 15 in., dendrites; and the remainder, columns and needles. According to Nakaya, irregular assemblages of columns and plates form over the temperature ranges − 9° C. to − 14° C. and − 17° C. to − 20° C.; dendrites form in the temperature range − 14° C. to − 17° C.

Since it is very difficult to estimate the temperature of formation of the snow, and since this temperature is not likely to remain constant throughout a snowfall, any conclusions drawn based on details in the observe distributions must indeed be speculative.

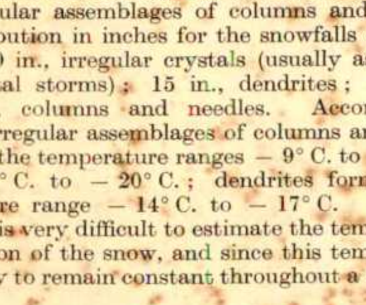

Fig. 2. Dependence of snowfall on temperature from observations made at Montreal

Results of Gravitational Significance in Riemannian Geometry

IT is well known that by contraction one can deduce from the Bianchi identities in Riemannian geometry the following result:

$$R^h{}_{ijk\,;\,h} = R_{ij\,;\,k} - R_{ik\,;\,j} \qquad (1$$

From this it follows that if:

$$R_{ij} = \lambda g_{ij} \qquad (2$$

which is the usual condition for an Einstein space then:

$$R^h{}_{ijk\,;\,h} = 0 \qquad (3)$$

This implies:

$$\text{(i)}\quad C^h{}_{ijk\,;\,h} = 0, \quad \text{(ii)}\quad W^h{}_{ijk\,;\,h} = 0 \qquad (4)$$

for the conformal and projective curvature tensors in Eisenhart's[1] notation. The gravitational significance of (3) and (4) does not appear to have been examined so far, although (4i) has received some attention in a particular context[2].

For an arbitrary contravariant vector field a^m we have:

$$a^m{}_{;\,ln} - a^m{}_{;\,nl} = a^p R^m{}_{pnl} \qquad (5)$$

Hence, by contraction ($m = l$), we get:

$$a^m{}_{;\,mn} - a^m{}_{;\,nm} = a^p R_{pn} \qquad (6)$$

If now (2) is used, (6) is reduced to:

$$a^m{}_{;\,mn} - a^m{}_{;\,nm} = \lambda a_n \qquad (7)$$

The cosmological constant λ is now given by:

$$\lambda = a^n(a^m{}_{;\,mn} - a^m{}_{;\,nm})/a^l a_l \qquad (8)$$

which shows how the constant can be interpreted in terms of operations on an arbitrary non-null vector field a^n. From (7) we can also deduce that:

$$a^m{}_{;\,nml} - a^m{}_{;\,lmn} = \lambda(a_{l\,;\,n} - a_{n\,;\,l}) \qquad (9)$$

If the gravitational field is given by $R_{ij} = 0$, the essence of the equations is contained in the fact that an arbitrary vector field a^n satisfies the condition:

$$a^m{}_{;\,mn} - a^m{}_{;\,nm} = 0 \qquad (10)$$

It is believed that the gravitational significance of (8) and (10) has not been noticed so far.

FORTHCOMING EVENTS

Monday, June 18

RITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF NCE GROUP (in the Joint Staff Common Room, University College, er Street, London, W.C.1), at 5.30 p.m.—Dr. A. W. Stonier: e Influence of Philosophy in Economics".

Wednesday, June 20

STITUTE OF NAVIGATION (at the Geographical Society, 1 Kensing Gore, London, S.W.7), at 5 p.m.—Mr. George Lowe. "Crossing tarctica".

OYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, .7), at 5 p.m.—Special General Meeting to elect Officers and ncil for 1956–57. Mr. N. A. Phillips: "The General Circulation of Atmosphere—a Numerical Experiment".

Wednesday, June 20—Thursday, June 21

OLAROGRAPHIC SOCIETY (in the Chemistry Lecture Theatre, tersea Polytechnic, Battersea Park Road, London, S.W.11), at .m. daily—Symposium on "Polarography and Medicine".

Thursday, June 21

OYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson use, 26 Portland Place, London, W.1), at 7.30 p.m.—Annual eral Meeting; followed by Prof. P. C. C. Garnham: "Looking Parasites in Brazil—an Illustrated Account of a Journey".

APPOINTMENTS VACANT

PPLICATIONS are invited for the following appointments on or ore the dates mentioned:

ASSISTANT LECTURER IN PSYCHOLOGY—The Secretary, The Queen's iversity, Belfast (June 20).

LECTURER (with a good degree and suitable teaching experience) MATHEMATICS—The Principal, Leeds College of Technology, okridge Street, Leeds 2 (June 20).

SENIOR ENTOMOLOGIST, and an ENTOMOLOGIST, IN THE DEPARTMENT RESEARCH AND SPECIALIST SERVICES, Federal Ministry of Agri-ture, Federation of Rhodesia and Nyasaland—The Secretary, odesia House, 429 Strand, London, W.C.2 (June 20).

ASSISTANT, Grade B (with teaching and research experience) IN OLOGY—The Clerk to the Governors, Chelsea Polytechnic, Manresa ad, London, S.W.3 (June 23).

BIOCHEMIST (honours science graduate) for research duties in the riatric Department of the Sunderland Hospital Group—The Senior ministrative Medical Officer, Newcastle Regional Hospital Board, lker Gate Hospital, Benfield Road, Newcastle-upon-Tyne 6 (June).

CHEMIST (with a first- or good second-class honours degree or equiv-nt qualification and at least three years experience, and preferably nowledge of liquid fuels and lubricants) at the Central Laboratory, iswick—The Recruitment and Training Officer (F/EV.587), London nsport, 55 Broadway, London, S.W.1 (June 23).

RESEARCH ASSISTANT (with a good honours degree in physics and ferably some research experience) IN THE PHYSICS DEPARTMENT—e Head of the Physics Department, Imperial College of Science and chnology, London, S.W.7 (June 27).

STATISTICIAN or MATHEMATICIAN (preferably with a university gree in mathematics or statistics or equivalent qualifications) at adquarters, London, S.E.1, to assist in a section devoted to system eration research, and will be expected to apply original mathematical as to the short-term and long-term planning of the system—The rector of Establishments, Central Electricity Authority, Winsley eet, London, W.1, quoting Ref. AE 832 (June 29).

ASSISTANT FORESTERS and FORESTERS (graduates of a recognized estry school), to assist in the management of large-scale softwood ntations, including establishment maintenance, protection and lization, or assist in research—The Agent General for South Aus-lia, South Australia House, Marble Arch, London, W.1 (June 30).

ASSISTANT LECTURER (graduate in physics, chemistry, metallurgy, logy or engineering) IN DENTAL MATERIALS—The Registrar, The iversity, Manchester 13 (June 30).

ASSISTANT LECTURER (with special qualifications either in mycology d soil microbiology or in plant physiology) IN THE DEPARTMENT BOTANY—The Registrar, The University, Bristol (June 30).

DIRECTOR OF THE COMPUTING LABORATORY, situated in Newcastle-on-Tyne—The Registrar, University Office, 46 North Bailey, rham (June 30).

LECTURER IN ENGINEERING (Civil)—The Registrar, The University, anchester 13 (June 30).

LECTURER IN GEOGRAPHY, and a LECTURER IN CHEMISTRY, at the gerian College of Arts, Science and Technology—The Secretary, visory Committee on Colonial Colleges, 1 Woburn Square, London, .C.1 (June 30).

RESEARCH ASSISTANT (with a degree in agriculture, with special erence to animal husbandry or production), for investigations on ccase quality of beef—The Secretary, School of Agriculture, The iversity, Cambridge (June 30).

TECHNICAL ASSISTANT (Display) IN THE DEPARTMENT OF ARCHÆO-GY AND ETHNOLOGY; and a TECHNICAL ASSISTANT IN THE DE-RTMENT OF NATURAL HISTORY—The Director, Liverpool Public useums, Carnatic Hall, Elmswood Road, Liverpool 18 (June 30).

RESEARCH STUDENTS (with a degree of Bachelor or Master of a British university, other than Manchester) IN SCIENCE—The Registrar, The University, Manchester 13 (July 1).

LECTURER or ASSISTANT LECTURER (with special interest in inorganic chemistry) IN CHEMISTRY—The Registrar, The University, Sheffield (July 2).

SENIOR LECTURER, LECTURER, and ASSISTANT LECTURER IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Manchester 13 (July 4).

ASSISTANT LECTURER (with an honours degree) IN PSYCHOLOGY—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (July 6).

LECTURER or ASSISTANT LECTURER IN MATHEMATICS, at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 6).

READER IN ELECTRICAL ENGINEERING at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 6).

SOIL ANALYST (with a degree or equivalent qualification in chemistry, and at least two years subsequent experience), at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 6).

SOIL MICROBIOLOGIST (with a good honours degree and practical experience)—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (July 6).

ASSISTANT (male, with a degree in horticulture, agriculture or botany, together with a keen interest in the scientific aspects of practical fruit culture, and ability to convey the results of research to scientists, advisory officers and growers) IN THE SCIENTIFIC LIAISON SECTION—The Secretary, East Malling Research Station, near Maidstone, Kent (July 7).

PRINCIPAL (male, graduate of a British university, with teaching and, if possible, some administrative and industrial experience) OF THE BRADFORD TECHNICAL COLLEGE—The Director of Education, Town Hall, Bradford 1 (July 7).

SENIOR LECTURER IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Sheffield (July 7).

DEMONSTRATOR or ASSISTANT LECTURER (with a medical qualification registrable in this country) IN PHYSIOLOGY—The Registrar, The University, Manchester 13 (July 9).

ASSISTANT (preferably with qualifications in psychology) IN THE DEPARTMENT OF LOGIC AND METAPHYSICS in St. Salvator's College, St. Andrews—The Joint Clerk to the University Court, College Gate, St. Andrews (July 14).

LECTURER or ASSISTANT LECTURER (with qualifications in physical or inorganic chemistry, and preferably with experience in radiochemistry) IN CHEMISTRY—The Registrar, The University, Hull (July 16).

FELLOW AND TUTOR IN PHYSICS—The Warden, Merton College, Oxford (July 23).

CHAIR OF CHEMISTRY at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31).

LECTURER IN THE DEPARTMENT OF PHILOSOPHY, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31).

LECTURER IN GEOGRAPHY—The Secretary, The University, Aberdeen (September 5).

ASSISTANT REGIONAL TRIALS OFFICER (graduate in botany or agriculture, and preferably practical experience in crop production), at Leeds University Farm, Headley Hall, Yorks—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

CHEMIST (with a first- or good second-class honours degree in chemistry) with the Geological Survey of Uganda, for the analysis of ores, rocks and minerals with particular reference to the ores of tungsten, beryl, niobium and tantalum and analyses of limestones, and to work in close co-operation with the department's ore-dressing laboratory—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD 105/9/06.

DEPUTY DIRECTOR OF RESEARCH—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22.

MASTER TO TEACH PHYSICS including advanced and scholarship levels—The Headmaster, Bishop's Stortford College, Herts.

PHYSICISTS (with, or obtaining, a first- or second-class honours degree or equivalent qualifications) at Ministry of Supply Research and Development Establishments, in the South Midlands and the South of England, for work directed towards the solution of problems and the development of new ideas in the fields of radio communications, radar, guided missiles, aircraft and aircraft equipment, gas turbines, instrumentation, etc.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.214/6A.

PHYSICS LABORATORY TECHNICIAN, for duties concerned with the application of physics to medical problems, maintenance and service of electrical equipment, including high-voltage X-ray sets and electronic equipment used with radioactive isotope work—The Group Secretary, War Memorial Hospital, Scunthorpe.

RESEARCH ASSISTANT (honours science graduate), to work on the chemical and biochemical aspects of cancer research—The Director of Cancer Research, Department of Pathology, Medical School, The University, Birmingham 15.

RESEARCH OFFICERS (preferably with an honours degree in mining, metallurgy or chemical engineering and/or postgraduate experience) IN THE MINES DEPARTMENT, Federation of Malaya, for research into mining and mineral dressing problems and the application of results, through pilot stages, to utilization in the field—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.99/23/01.

SENIOR LABORATORY TECHNICIAN IN THE CLINICAL PATHOLOGICAL LABORATORY, for duties which will be mainly biochemical—The Secretary, The National Hospital, Queen Square, London, W.C.1.

DIFCO

PEPTONES AND HYDROLYSATES

for Microbiological Culture Media

Difco peptones and hydrolysates are prepared to meet the diversified nutritional and biochemical requirements of microorganisms. A single peptone cannot provide the essential nitrogenous nutriments for all cultural and metabolic processes. Difco peptones and hydrolysates have been developed to meet the various requirements for microbiological procedures including growth, preparation of toxin and vaccines, and for the study of microbial metabolism.

Eighth International Series of

Progress in Nuclear Energy

Extract from the foreword for Volume I Series III
PROCESS CHEMISTRY by Sir Harold Hartley

"The release of so much information and the clarification of ideas resulting from the discussions at Geneva did much to advance the development of power reactors. The series . . . now being published by the Pergamon Press containing both surveys of the advances in certain fields and also some of the papers presented at Geneva in a revised form will help to make all the new knowledge quickly available."

Extract from the foreword for Volume I Series II
PROCESS CHEMISTRY by Glen. T. Seaborg

"The competitive economic position of nuclear power compared to other sources of energy will, in many parts of the world, depend in large measure on how the problems in chemical processing are ultimately solved. This volume is a very timely progress report on this extremely important aspect of the growing nuclear energy industry. It was made possible by the very fortunate declassification of the large amount of engineering information presented at the International Conference on Peaceful Uses of Atomic Energy held at Geneva, Switzerland."

Descriptive prospectus sent on request.

Without obligation books may be ordered for ten days free examination (U.K. and EIRE ONLY)

We regret that, in the last issue, this volume was incorrectly announced as already published.

ENCE COLLEGE

AUTOMATION AND MANAGEMENT

THE report on the technical trends of automation and their impact on management and labour ich the Department of Scientific and Industrial search has prepared*, and on which the two major litical parties in the House of Commons con- atulated the Department on May 17, does not add nificantly to our technical knowledge of auto- tion. It is important, nevertheless, first as helping minimize the dangers which attend the misunder- andings of the nature and implications of auto- ation and which have already led to its becoming mething of a bogey word; and secondly, it gives convenient summary of the present position of our owledge of the expansion of the scope of mechan- tion, of the development of techniques of auto- atic control and especially of the application of e electronic digital computer to the automatic ocessing of technical information and more par- ularly of the social and human problems which are volved both for managers and for the trade unions. this context, the Duke of Edinburgh's Study onference on Human Problems of Industrial Com- unities within the Commonwealth and Empire to held in Oxford during July 9–27 assumes additional portance.

All these meanings are popularly given to auto- ation, and the report accordingly covers all technical evelopments that make automatic production more ssible. Although the confusion between these fferent meanings has been responsible for mis- derstandings and for some opposition to what is sentially a development that has been in progress r centuries, the report should clarify some at least the confusion and help to abate tension. Auto- ation is put into its proper historical perspective. so far as, like the Minister of Labour in his broad- st on May 4, we restrict its meaning to "machines oking after machines", it only represents the third three continuous and overlapping phases in the evelopment of modern industry. The electronic gital computer, by facilitating the rapid and auto- atic processing of business information, has tended automatic control to complex manufac- uring operations and commercial offices. The pace development has been accelerated; but the principle d techniques of automatic control were already eing developed and applied to manufacturing pro- esses over a widening range of industries. In its urn, such automatic control both followed and roceeded simultaneously with the earlier phase of ne production in which advanced techniques of andling materials and products and assembling omponents had extended the scope of the earlier hase of mechanization.

It is the scale of future developments that has ade automation something of a bogey. It is already ossible to envisage a large and complex, yet fully automatic, factory in which a computer integrates and controls the separate automatic production lines, and almost certainly striking developments in automatic control will come from units incorporating computers. The potential scale of such developments and the economy in labour they seem to offer are reasons for the present concern; the fact that they affect primarily those industries which are turning to mass production and, in thus offering mass consumption, are most sensitive to fiscal and economic policy, is another. The third and most important reason is psychological, arising in part from the shadow cast upon full employment and in part from inherited prejudices and imperfectly understood events of the past.

The report begins by looking at automation in historical perspective, and briefly outlining the conception of automatic production with two examples, one a piston factory in the U.S.S.R., and the other a building-board factory in the United Kingdom. These examples represent the converging of two or more developments; but current progress is mainly in separate streams—transfer machines, mechanical handling and assembly, automatic control of machinery and processes, and clerical work by electronic computers. These all help to make more processes automatic, but do not integrate them and thus do not fulfil the concept of fully automatic production. The present position is accordingly indicated in a chapter on the technical trends, which examines separately developments in automatic machinery, including the control of machine tools by electronic methods in automatic process control, and in the automatic processing of data.

In this chapter some of the future possibilities are discussed; but they are considered more fully in the succeeding chapter on the extent and rate of development. Control equipment in a new chemical plant or petroleum refinery may represent as much as 20 per cent of the entire capital equipment in terms of cost, and in future it should be possible on an electronic computer to integrate with the direct control of all variables in the process and plant the time-consuming calculations needed to assess the effects of deliberate changes in operating conditions, raw materials and plant characteristics. Moreover, if the present trend is followed, much process control of the future will be based on the measurement of quality in the final product, though not until techniques of instrumentation are much further advanced. While computers will almost certainly be introduced gradually in offices, it can already be assumed that there is much scope for them; but their use will call for careful re-examination of office routines and may change them in many ways, not only replacing clerical staff but also permitting the production of data that could not be obtained in time to be useful before, if obtainable at all.

The report suggests that, while it is uncertain how far and how fast automation will proceed, many industries will adopt automatic techniques of production in one form or another. Neither size of firm nor availability of capital appears to be a principal restriction, though progress is likely to be most rapid in the bigger firms with the advantages of larger-scale production and bigger financial resources. The most decisive factor is likely to be the shortage of trained managers, engineers and technicians, partly because of the increasing technical complexity of industrial production and partly because of the existing shortage of scientists and technologists. Indeed, the report goes so far as to suggest that a major re-appraisal of university and vocational training in Britain may be needed.

---

* Department of Scientific and Industrial Research. Automation: Report on the Technical Trends and Their Impact on Management nd Labour. Pp. viii+106 (London: H.M. Stationery Office, 1956.) s. net.

That conclusion emerges equally clearly in the chapter which considers the impact on management. This chapter and the succeeding one, which discusses the impact on labour, may well be the two most important in the book. They both point to the imperfections of present knowledge of the economic and social aspects of automation when compared with knowledge of the technical possibilities, and to the vital need of extending knowledge of these aspects by research and exchange of experience. Here, particularly, however, the report is not entirely uninhibited, and it is difficult to believe that its authors have been so lacking in discernment as might be suggested by the absence of comment or suggestions for inquiry into, for example, the problems of trade union demarcation that any wide programme of re-training adult workers is bound to encounter, or the new flexibility in union rules and in some employers' recruitment policies that will be required. Such lacunæ are the more obvious when the list of suggested subjects for research into the social and economic aspects is examined. The recent work of B. C. Roberts, J. A. Mack, H. A. Clegg and A. Flanders, and of others like N. S. Ross and R. Harle, writing in the recent special issue of *The Political Quarterly*, has shown how, if the trade unions are to adapt themselves to fulfil more effectively their new role in the Welfare State, it must be as a result of inquiry and reform from within. It will not be secured, however, by ignoring necessity for change and inquiry, or by failing to point out the directions in which they are required; and the report is notably weak in throwing on management the whole responsibility for difficulties attendant on the introduction of automation, and also in its reluctance to point out directions in which the co-operation and support of the workers are no less essential.

Except in relation to the new skills required, the chapter on labour does not draw any general conclusion pointing to responsibilities on the part of trade unions or workers. Operators on present-day automatic processes need no advanced technical training; but they must learn to understand their processes and machines. They may need more or less skill than formerly; but there is rarely a sharp break with existing skills. The evidence suggests that the new operative skills can be acquired through a moderate degree of training on the job. On the need for flexibility the report is silent; but it suggests that automation is likely to provide real substitutes for satisfactions which have already di appeared from jobs that it is likely to eliminate. Th operator will often see more of the process, receive wider range of technical information, because h must understand how his own job fits in with othe on the same process, and in these and other way his work is likely to be more interesting. This ma be the more important in that by calling for educa tional qualifications in a great proportion of job automation may make it more difficult to advan merely through experience gained on the job.

The new technical and managerial skills—includin those of programmers, 'systems' engineers, mai tenance craftsmen and more highly trained manage —are less easily acquired. If they are taken int account, the general level of skill will tend to rise the sectors of industry affected by automatio especially where routine clerical work is taken ove by electronic digital computers. In some industri even supervisors may require qualifications that ca only be obtained at educational institutes, and th report emphasizes the importance of firms seeking t train and promote the potential managers and technicians of all grades who are still in the ranks. Moreover, co-operation among technical specialists, an between them and managers, on one hand, an maintenance craftsmen and operatives on the othe becomes increasingly important; technical co-operation with maintenance men and technica management may provide a new social satisfactio for the operatives on automatic processes, who ar often spread thinly over a big area and may find i keeping the machine-line or process running a satisfaction they might formerly have found in membership of an operative team.

The bearing of all this on the expansion of technica education is obvious. The implications for educational policy are no less important, and the report a a whole emphasizes the vital importance of plannin educational expansion as a unity. If qualities lik versatility, adaptability and the capacity for understanding other points of view look like bein increasingly valued in managers and professiona staff, in a lesser degree they are called for in other also. Consultation with the trade unions in advanc of each step and the most careful attention to th needs, feelings and problems of the workers concerne will not ease the transition to automation if th workers are unwilling or unable to respond and ar incapable of seeing the problem against the perspective of the position of the industry and the need of the nation as a whole rather than of any on section of it.

So far as factory management is concerned, automation greatly increases the need for planning in order to minimize the technical inflexibility of highl integrated plant, to establish maintenance aimin at preventing faults, thus minimizing stoppages an achieving a high and constant rate of output, an providing for continuous running of machinery Existing techniques of management may need t give way to new techniques that suit automati processes, as, for example, in the systematic stud of operations, the use of computers and the contro f costs. Again, the necessary changes in operative ills will be made more smoothly if they are care- lly planned, if proper provision is made for training the job, and if workers are consulted and kept ell informed of likely developments. Moreover, ise management offers the best hope of surmounting ifficulties in persuading workers to accept the shift- ork essential for continuous running and in main- aining the workers' interest in the job without the egular social contact which the traditional operative eams afford.

These aspects of the tasks of management under e impact of automatic techniques of production ow how important it is that technological education ould be broadly based, and associated so far as ossible with those types of courses which in the ast have proved so successful in developing adminis- ative ability and the capacity for initiative, the cceptance of responsibility and powers of leadership. f the need for communication and co-operation in dustry is greatly increased, as this report suggests, xcessive specialization in order to provide technical nowledge may be a danger rather than a help unless hese qualities are safeguarded. Vision and imag- ation as well as versatility and adaptability will be equired, if management is to soften the impact of utomation on labour. All grades of management ill indeed require fuller knowledge of the technical actors that influence their decisions; and while it will e more important than ever to plan the construction f a new plant well in advance, such planning must ake account not merely of the technical com- lexities and aspects of production, but equally of he problems of organization of labour, including the lanning of man-power requirements and the avoid- nce of redundancies where possible by utilizing, for xample, natural wastage and labour turnover.

A number of the suggestions for research appended o the report are relevant to problems of management. or example, there is research into the economics nd social implications of shift-working, on which a tart has already been made at the Universities of heffield and Cambridge. At the South-East Essex echnical College and at the University of Edinburgh, ork has already been started into the forms of anagement structure and organization most effective ith automatic processes; but other work is sug- ested into the new techniques of management equired by automation and into methods of planning an-power requirements, for example, the planning f innovations to coincide with natural fluctuations n the labour force.

Like other developments that increase the com- lexity of techniques of production, automation akes it essential that scientists and technologists hould be given their right place in management, ecause technical considerations affect an increasing umber of policy decisions on investment and on the outine operation of plant. Managements require a road understanding of the new principles emerging rom scientific and technical developments, and echnologists and scientists require a clearer under- tanding of the economic and other managerial factors involved in implementing technical views. The report itself suggests that scientists and technologists are likely to be found at board-level more frequently than in the past, and some functional departments will increase in importance. It also queries the suitability in automation of the 'line-and-staff' principle of responsibility, though more by way of a matter for inquiry.

Much of this has been urged by Dr. P. V. R. Venables, by Sir John Cockcroft in his address to the Institute of Physics last April on "Science and Technology in Industry" and by others; both the Rector of the Imperial College of Science and Technology and the Principal of the Manchester College of Technology have indicated that the projected expansion at both Colleges is planned to provide technologists of the outlook and calibre demanded. Lord Heyworth again, at the annual meeting of Unilever, Ltd., on May 24, specially stressed the importance of good managers in industry, devoting most of his speech to their selection, background and training. If the Department of Scientific and Industrial Research's report on automation in the first place points to the urgent need for inquiry into the human and social aspects of automation, it equally presents the problem of finding managers of to-morrow of the requisite competence as one of the leading questions of the day. The report will have served its purpose if it brings the Government to a belated appreciation of the critical importance of that question.

As already emphasized, the report, however, also demonstrates the importance of looking at the expansion of education as a whole. It shows how vitally important to the economic and industrial future of Britain is the expansion not merely of technological education but also of technical education, and as a corollary the public understanding of technological change and what it involves. The Government has done well, as indicated in the reply of the Parliamentary Secretary to the Ministry of Labour and National Service to a question in the House of Commons on May 29, to promote the publication of a simplified version of the report for wide circulation, and there is much more needed to remove misunderstandings and fears of redundancy while the National Joint Advisory Council is considering the implications of the report itself. But the Government cannot rest there. It should be implementing, on an adequate scale, from our own resources and not merely from funds provided by American generosity, the researches into the economic and social aspects of automation which the report suggests. Even more important, it should be handling the educational issues with real determination and imagination, and no longer allow prejudice and tradition to impede the formulation and execution of a national policy adequate alike in scope, in content and in the resources with which it is provided. Lastly, the Government should be facing the issues involved in re-training and mobility of labour, so that its assistance policies do not subsidize under-employment and resistance to change but afford real help to those affected in the difficult period of transition from one job to another.

GEORGIUS AGRICOLA

Georgius Agricola 1494–1555 zu seinem 400 Todestag, 21 November 1955

(Deutsche Akademie der Wissenschaften zu Berlin.) Pp. 376+23 plates. (Berlin: Akademie-Verlag, 1955.) 38 D. marks.

De Natura Fossilium (Textbook of Mineralogy)

By Georgius Agricola. Translated from the First Latin Edition of 1546 by Mark Chance Bandy and Jean A. Bandy. (Geological Society of America Special Paper 63.) Pp. xiii+240. (New York: Geological Society of America, 1955.) 3 dollars.

THE four hundredth anniversary of the death of Georgius Agricola[1] (1494–1555) has been marked in Eastern Germany by the publication, under the auspices of the German Academy of Sciences at Berlin, of a commemorative volume containing twenty-five essays concerning various aspects of his life, work and times. Agricola was a man of varied accomplishments—one of the great scientists of the sixteenth century and also physician, scholar and diplomat—and these essays should have a wide appeal.

It is impossible, within the limits of a short review, to do more than refer briefly to the subject-matter of individual essays. The first, by Prof. Leo Stern, of Halle, is of an introductory character, dealing generally with Agricola's life and mentioning the many contemporary scholars whose work in some way impinged on his. Other essays cover particular periods in his life, and one which calls for special mention is the account, by Dr. Helmut Wilsdorf, of Freiberg, of Agricola's *Wanderjahre* in Italy and some of the English scholars whom he may have met there. The contemporary background is also discussed in articles on mineral collectors and collections of the sixteenth century, and on the songs of the miners; and a brief account of the miner and his work as delineated in contemporary art is accompanied by a number of attractive plates. One of these illustrates the beautiful frontispiece of the famous "Kuttenberger Kanzionale" (a manuscript volume of old songs in the possession of the Vienna National Library), depicting the whole gamut of mining activities, from the miner deep in the mine to the eager shareholders receiving their profits. Both this plate and that of the miners' altar at Annaberg would have gained immensely by reproduction in colour.

Many of the contributions are reviews, by experts, of different chapters in Agricola's most famous book, the "De Re Metallica". These deal with subjects such as mining law, mine machinery, ore-dressing, metallurgy and surveying in the sixteenth century. Among them is a valuable contribution by Dr.-Ing. P. Beyersdorfer, a glass technologist, comparing the account of glass manufacture given by Biringuccio in his "Pirotechnia" (1540) with that given by Agricola. A well-illustrated article on the woodcuts in the "De Re Metallica", by Dr.-Ing. W. Pieper, includes a reference to the suggestion, recently made by Dr. H. Prescher, that Agricola himself is represented in one of the woodcuts depicting tin-smelting, by a figure industriously writing in a note-book (p. 415 in the Hoover (1912) translation).

There are several essays on the influence exerted by the work of Agricola on mining in neighbouring countries, including one on the development of mining in Russia from the sixteenth to eighteenth centuries. This stresses the value attached to Agr cola's writings by the great Russian scientis Lomonossov.

Agricola published all his specifically geological an mineralogical writings together in one volume, in 1546 the work being generally known by the title of the firs part, "De Ortu et Causis Subterraneorum". The contents of this volume have unfortunately received muc less attention than they deserve. Dr.-Ing. Walthe Fischer, in an essay entitled "Agricola, Father o Mineralogy", discusses the valuable contributions t mineral science found in "De Natura Fossilium", th third section of this volume, and also mentions som of Agricola's opinions on such subjects as volcanoes earthquakes and ore-genesis; but one could hav wished for a fuller treatment of these subjects Another section in the same volume, with the titl "De Veteribus et Novis Metallis", a valuable historica account of mines, is discussed in a second essay b Dr. Wilsdorf, who advances the claim that Agricol laid the foundation for a history of mining.

Other aspects of Agricola's life are described in articles on his work as physician, on his books on money and on weights and measures, and on hi services as burgomaster of Chemnitz (now known a Karl-Marx-Stadt). The volume also includes an annotated record of Agricola's known correspondence published and unpublished, with a reproduction o his handwriting. There is no index, and the volume ends with a somewhat over-elaborate table of the various editions of Agricola's numerous publications This is useful, but its value would have been greatly enhanced if more bibliographical details had been given.

This commemorative volume is of especial value as a detailed study of mining and related activities in central Europe during the sixteenth century, but it should also have a considerable appeal to all interested in the development of science during that period.

In America, an appreciation of early mining and metallurgical classics has been manifest for a number of years. This interest was first stimulated by the publication of the well-known translation of Agricola's "De Re Metallica" by the Hoovers in 1912 Since then there have come in succession from the United States scholarly translations of A. A. Barba's "Arte de los Metales", of Biringuccio's "Pirotechnia", of early sixteenth-century editions of the mining and assaying works known as the "Bergbüchlein" and "Probierbüchlein", respectively, and of Lazarus Ercker's "Treatise on Ores and Assaying". Now the Geological Society of America has entered this field by publishing a translation, by M. C. and J. A. Bandy, of Agricola's "De Natura Fossilium". The translation has been made from the first edition, published in 1546, and not from the second edition, which was enlarged by Agricola himself, although not published until 1558, three years after his death. This treatise on minerals forms the third section in the volume of Agricola's geological and mineralogical writings mentioned above, and in it the term "fossilia" is used to include anything inorganic dug out of the earth. We find, therefore, not only accounts of minerals, but also of clays, and their use by potters and sculptors, of marls, and their use by farmers, of bricks, marbles, and even of incinerary urns. Although Agricola frequently quotes Pliny and other early authors, he adds many interesting comments of his own, such as "Within the year thirty-five buildings in Magdeburg have had lead roofs put on them", a statement which iggests this book might be of interest to economic istorians.

While this translation is most welcome, one misses e many scholarly notes that form so valuable a rt of the Hoovers' work. Many of their notes do, fact, refer to the "De Natura Fossilium", and some oss-reference to them would have been useful to e reader. However, a number of explanatory foot- otes have been included with this translation, as ell as indexes of mineral names in English, Latin d Greek. There is, unfortunately, no index of ace-names. A few misprints and errors have been oticed, such as "agate" on p. 18, line 33, for aetites".

This little volume should have a wide circulation, nd it is to be hoped it will be followed by translations to English of other works by Agricola, particularly e "Bermannus" of 1530, of which a new German anslation, by Dr. Wilsdorf, appeared as recently as 955.

WISCONSIN SYMPOSIUM ON SOLAR ENERGY, 1953

olar Energy Research

dited by Farrington Daniels and John A. Duffie. p. xv+290+11 plates. (London: Thames and udson, Ltd., 1955.) 30*s*. net.

RESEARCH on the utilization of solar energy has received a very great impetus as a result of onferences that have been recently held in Arizona ee *Nature*, Jan. 21, p. 110). This book is a record f the proceedings of an earlier conference organized y Prof. Farrington Daniels at the University of Visconsin, Madison, in September 1953. Though ess ambitious than the Arizona meetings, the adison conference offered the first opportunity for any of those actively engaged in solar research to ome together and discuss their problems. The book onsists of a series of chapters written by those ttending the conference or invited to contribute, nd covers most of the aspects of the utilization of olar energy. These may be summarized briefly nder the following headings: collection of solar adiation in the form of low-grade heat (that is, below he normal boiling point of water, as used for water nd house heating, and water distillation); concen- ation of the radiation by mirrors to produce high emperatures for melting metals and refractory aterials; conversion of radiation to electricity, ither by thermoelectric methods with heat as an itermediate stage, or by photovoltaic effects; hotochemical effects in which the equilibrium f a chemical system is changed by the action of ght; and photosynthetic processes through living lants.

An introduction by Prof. Farrington Daniels xplains the object of the conference and is followed y a section on probable world energy demands in e future, in which P. C. Putnam predicts that in a undred years time solar heat collectors might supply early 10 per cent of the world's demand in the form f low-grade heat, though only 0·1 per cent in the rm of power. Incidentally, 60 per cent is quoted r nuclear fuels and 25 per cent for fossil fuels. nowledge of the influence of meteorology on solar adiation and measurement of solar radiation are essential for a study of applications, and these factors are discussed in the succeeding chapters.

The nine chapters which follow collate papers on space heating and domestic uses of solar energy; solar power, solar evaporation and distillation, atmospheric phenomena and conversion of solar to electrical energy, solar furnaces, photosynthetic and photochemical utilization of solar energy, the British point of view, and miscellaneous applications and suggestions for further work. An appendix by Dr. John A. Duffie, of the University of Wisconsin, contains a survey of United States patents on the subject and a bibliography. Most of the sections consist of three or four papers by well-known research workers on the subject, and describe in a clear and lucid manner the present state of knowledge and the future possibilities.

The object of the symposium was to summarize the situation regarding the utilization of solar energy, and it is possible that the recent world conference in Arizona was, in some respects, promoted by the interest aroused at this earlier meeting. Many people with thoughts on the future development of world energy resources are inquiring about the possibilities of utilizing solar energy directly. The contents of this book appear to have been arranged for the express purpose of explaining these, and are written in an easily readable style with adequate illustrations. The complete volume gives the best outline at present available of activities in the utilization of solar energy.

THERMODYNAMICS FOR CHEMISTS AND CHEMICAL ENGINEERS

The Principles of Chemical Equilibrium, with Applications in Chemistry and Chemical Engineering

By Prof. Kenneth Denbigh. Pp. xxi+491. (Cambridge: At the University Press, 1955.) 42*s*. net.

AN understanding of thermodynamics is essential for all who are concerned with quantitative aspects of chemical processes, and yet most students find its concepts too abstract for rapid assimilation. A major difficulty is that the link between thermodynamics and the familiar and easily comprehended molecular theory is statistical mechanics, and most teachers, and apparently most authors, are of the opinion that the student is even less receptive to this subject. The order of presentation of most courses of physical chemistry is therefore molecular theory, thermodynamics and, finally, statistical mechanics. One wonders whether the problem of presentation is not the root of the vast number of books on thermodynamics and whether this spate of texts, each one of which may have a different emphasis, approach and nomenclature, is not a further barrier to the understanding of the often benumbed student. Every teacher of this fascinating and fundamental subject must be assailed by doubts of this kind when he opens the pages of yet another volume.

None the less, Prof. Kenneth Denbigh's book is a welcome addition to the multitude. It is intended for students in their final year of a chemistry or a chemical-engineering degree course, who have already had some acquaintance with the elementary parts of the subject. The first part (100 pages) introduces the first and second laws, the usual thermodynamic functions and conditions of equilibrium, while the second (214 pages) is concerned with the application to gases, gaseous equilibria, phase equilibria and solutions. The approach throughout is properly based on the chemical potential, and the treatment, always adequate, is at times illuminating. The student who works through these chapters will be amply rewarded; but work he will have to, for although care has been taken to ensure clarity, the style is at times ponderous and he may well get the impression that the subject is more difficult than it really is. He will be helped, however, by the illustrations in the text and by the graded problems at the end of each chapter—a very valuable feature of the book. Only by submitting himself to the rigid discipline of working examples does the student begin to appreciate the value and versatility of the thermodynamic tool and to acquire the confidence to use it in attacking practical problems. The chemistry student will find the treatment of cells and electrolytes too brief and will regret the exclusion of surface phenomena. The third part (150 pages), devoted to statistical mechanics, contains interesting chapters on the statistical analogues of entropy and free energy, the partition functions of gases, and crystals and the third law, but the beginner may find them above his head. The two final chapters, one giving a brief treatment of regular solutions and adsorption, and the other on some aspects of chemical kinetics, might well have been replaced by a statistical treatment of chemical equilibrium, which receives only scant attention. There is even no mention of the functions $(G^0-H^0_0)/T$ and $(H^0-H^0_0)$ and of their use.

Prof. Denbigh's book will be useful to the brighter students and to teachers of the subject; but those applied chemists and chemical engineers who wish to be led gently up the thermodynamic slope may seek a less strenuous guide.

TOWARDS THE NEW CYTOLOGY

Physiologie der Zelle

Von Dr. Johannes Haas. Pp. 474. (Berlin-Nikolassee: Gebrüder Borntraeger, 1955.) 48 D.M.

THE need for a text-book presenting an integrated account of cell organization in the light of developments of the past twenty-five years has for some time been evident, and Dr. J. Haas's book goes a long way towards satisfying this need. The modernity of its approach is indicated by an initial section on molecular morphology, accounting for about one-third of the volume. There is to this extent a certain parallel with Frey-Wyssling's book, "Submicroscopic Morphology of Protoplasm and its Derivatives"; but there is a wealth of difference between the two, for the emphasis in Dr. Haas's book is primarily biochemical. Within the compass of a hundred and sixty pages he examines the structure and properties of proteins, nucleic acids, enzymes and lipoids, and then proceeds to a consideration of cell organelles: cytoplasm, cell surface, mitochondria, nucleus and interphase-chromosomes (119 pp.). In a third section he discusses selected cell functions: respiration, exchanges with the environment, cell division, growth and differentiation (155 pp.).

The extent to which the author has succeeded in integrating a work of this scope is highly commendable; but he has not managed to avoid repetition It would be easy to draw up a list of reference missed, and for British and American readers ther will be some shocks; but these omissions do no impair the over-all achievement. They are mor than offset by the number of references which will be new to many readers.

On a different plane of criticism, one may perhap regret that Dr. Haas seems not entirely conscious o the revolution in ideas which has occurred and o which he displays the results. He states (p. 17) tha the object of physiology is the study of function in its dependence on organic structure prevailing at given time. It is to be doubted whether any physiologist of thirty years ago would have so expressed hi aim; and there are probably many physiologist to-day who will be surprised by such a definition For cell physiology, the definition is a concise statement of present aims; but Dr. Haas allows it to pass as if it were a commonplace. Related to thi lack of historical awareness is a more serious criticism—the more serious since this book is clearly a text book—namely, that he frequently introduces a nev topic by a statement derived from classical cytological views, but made as if those views still retained their original force. Thus he quotes without commen (p. 170) Wilson's view that the structureless hyaloplasm is the most constant and active component o the cell, even though he is well aware of the exten to which this opinion requires modification in the light of the role of the mitochondria. Again, he repeats—and does so as if the generalization admitted of no exceptions—that "the living nucleus appear optically empty, both in normal light and dark ground". If students are to be spared the necessity of leaping old hurdles, it is the limited value of the light-microscopic image which requires emphasis and what is important is that the nucleus is *no* optically homogeneous when viewed by phase contrast. The reason for such statements is the difficulty we all experience of escaping from the somewhat mystical concepts of classical cytology the twin man-made ghosts, *the* nucleus and *th* cytoplasm, both homogeneous in the light-microscope—and by implication homogeneous in every other respect as well.

Not only in cytological matters, but also in the exposition of biochemical topics, Dr. Haas sometime modifies his initial position profoundly and disconcertingly at a later stage. Thus, the discussion o molecular shapes (p. 28 *et seq.*) proceeds as if chain molecules of the linear polypeptide or polysaccharide type were the only type of linear macromolecule known. Not until the discussion of cytoplasmic structure (p. 194) do we learn of polymerization o globular molecules to form fibrils.

Dr. Haas writes a simple German style of somewha unusually short sentences. Particularly successful sections are those on mitochondria, nucleus, cell respiration, growth and differentiation. It is eviden that considerations of cost have influenced both layout and the extreme economy of illustration. The latter is regrettable; for Dr. Haas's book, in spite o its title of 'cell physiology', is a 'cytology'. That i one indication of the distance travelled during the past twenty-five years; another is this, that the name of Boveri occurs but once, and without reference.

LAURENCE PICKEN

LEARNING IN MAN AND ANIMALS

THE discussion on "Learning in Man and Animals" on May 16, initiated by the Section of Comparative Medicine of the Royal Society of Medicine, fell into two relatively clearly differentiated parts. One of these might be called naturalistic-empirical; concern here is with field-observations and the direct assessment of certain experimental modifications. Dr. W. H. Thorpe's discussion of "Key Problems in Animals" is characteristic of this approach.

Dealing with the problem of instinct in animal learning, Dr. Thorpe pointed out the value of studying the songs of birds in this connexion, particularly in view of technical advances made in recent years (he instanced tape recordings and electronic methods of analysis). Some birds apparently have their song patterns determined completely by heredity, so that the self-same patterns are produced even when they are brought up in complete isolation. Other birds, such as chaffinches, react to such 'Kaspar Hauser' experiments in rather a different manner. The song pattern resembles that of birds brought up normally, in its broadest outline, but lacks all the finer modulations and modifications. If such birds are brought up in groups, they do learn to modify the original pattern until, finally, all the birds in the group produce patterns which are virtually indistinguishable from each other. These patterns do not change even when later on the birds are exposed to song patterns of free animals, and thus 'group learning' may account for the well-known facts of local dialects in chaffinches. Chaffinches do not learn the songs of other birds like, for example, bullfinches, who will learn almost any kind of pattern quite easily.

Regarding the learning ability of animals and particularly birds, Dr. Thorpe mentioned the recent work of Otto Köhler in Austria, who has studied the counting ability of birds and squirrels. Much of the previous work in this connexion has been vitiated because of accidental clues, and this recent work is notable because of its experimental rigour. In one group of experiments, jackdaws were taught to open a box having on it a number of dots corresponding with a number of dots on a key card presented to the animal. Great care was taken to vary the positions of cards and boxes, to randomize the size, shape and position of the dots, and in fact to eliminate all possible clues except that of number. Under these conditions it was proved conclusively that birds can compare groups of units and act in accordance with this information. The limit of this ability appeared to be in the neighbourhood of six or seven. This is an interesting finding in view of the fact that in human beings also the process of number estimation shows a definite break roughly at this number. Below it human beings appear to employ a process of what has been called 'subitizing', which is characterized by immediate, errorless, apprehension of number. Apparently birds possess this ability to the same extent as man; what they do not apparently possess is the additional ability to count. Learning along these lines appears to be quite reliable and accurate in birds. The interesting point was raised that there appears to be no obvious biological function which this ability serves, as the birds cannot be assumed ever to use number estimation in their natural habitat.

Mr. B. B. Boycott's paper on "The Neural Basis of Learning in *Octopus vulgaris*" dealt mainly with the abilities of octopus to learn to discriminate between different stimuli, and the effects on memory of the removal of parts of the vertical lobe. Discrimination learning was established by associating rewards (crabs) with one figure, and electric shock with another. Apparently the animals have no difficulty in establishing differential responses to black as opposed to white, to large as opposed to small, and to differences of position. They tend to fail in shape differentiation, as, for example, in discriminating between a square and a diamond, or a square and a circle.

Memory was studied after the removal of various parts of the vertical lobe, an important aspect of the experiment being that operations were carried out both before and after the original learning had taken place. The results indicated that the proportion of brain tissue removed had an important effect on the decrease in efficiency of performance, very much as had been found by Lashley, many years ago, in the case of rats. The results are difficult to interpret, however, because the experimenters failed to differentiate between learning and performance, using the latter as an index of the former. That this is inadmissible was shown quite clearly in one of the experiments described, in which it was found that an octopus after operation apparently lost all power of discrimination when the positive and negative stimuli were presented with the bait actually on them, but showed almost perfect discrimination when the stimuli were presented without the bait. In fact, there appears to be a close similarity between leucotomized humans and brain-operated octopus in terms of greater impulsiveness and lessened inhibition. These temperamental effects of brain damage are important and might be worthy of closer study.

The next two papers dealt rather with theoretical models in terms of which results of learning experiments can be analysed. While also concerned with experiments, it should be noted that adherence to this approach implies a rather different attitude compared with the naturalistic field-study type of approach, which in its extreme form appears to study facts for their own sake. To the theoretical psychologist the experimental demonstration or the empirical fact is important in so far as it contributes to a theoretical formulation or decides between several deductions from different theories. At the present stage of research on learning, both types of approaches are of obvious interest and value and serve mutually to complement each other.

In his discussion of "What Do We Learn ?", Dr. H. Kay was concerned with putting forward a version of what is sometimes called the probabilistic theory of learning. According to this way of looking at the learning process, past experience establishes certain expectancies according to which an individual judges the most probable sequel of any given stimulus. Such a model has obvious relevance to conditioning experiments, and Dr. Kay demonstrated for many everyday situations that an explanation of learning in terms of the dependent probabilities within a series of events can be made to appear reasonable. He extended this type of analysis to the learning of simple skills, showing how the learning of such simple acts as that of catching a ball can be interpreted in probabilistic terms.

The strength of such an approach lies in the ease with which quantitative analysis becomes possible; we can obviously measure probability of occurrence of a given act in terms of the relative frequency with which the act is in fact performed. The obvious weakness of the approach is two-fold. In the first place, the probability of an act changes with its performance, so that it is difficult to attribute any operational meaning to the probabilistic analysis in the case of the individual person. We can do so only in terms of groups of people, and it is doubtful to what extent the averaging of responses is permissible. It has been suggested that, as a general rule, averaging of response-rates is permissible only when the formula according to which growth takes place can be expanded by Taylor's theorem; this sets severe limits to this form of analysis. Another, and probably more fundamental, objection to this model is that it seems to leave psychology behind altogether by its complete failure to analyse the different components (drives, habits, etc.) which enter into the learning process.

As the last of the four papers, Prof. H. J. Eysenck's discussion of "Modern Learning Theory" presented a more orthodox type of model which has become widely accepted among psychologists. This model, which is due largely to the work of C. L. Hull, is a combination and formalization of two streams of thought, both of which are of considerable antiquity. One component is that of hedonism, or motivation by pain and pleasure; this was formalized and subjected to experimental study by Thorndike as the 'law of effect', and now emerges under the name of 'reinforcement' or 'drive reduction'. The other component is that of associationism; this was brought under experimental control by Pavlov and Beckterev, in the form of conditioning or habit formation. Hull joined these components in an impressive theoretical structure the formal character of which makes possible large numbers of experimental predictions, many of which have been verified. This approach, it should be stressed, is a purely molar one; the concepts are what psychologists call 'intervening variables' or 'hypothetical constructs' for which no neurological or physiological equivalent is necessaril postulated.

The most important concept in the theory is dissociation of performance (symbolized by Hull a ${}_SE_R$) from habit (symbolized as ${}_SH_R$). Habit i conceived as a relatively permanent modification o the nervous system which mediates all learning performance can only be used as an index of thi modification under certain conditions. To equate th two, as is often done by experimenters lackin psychological sophistication, is to invite disaster Much experimental work has been done on th conditions determining the growth of ${}_SH_R$, an among those found are: the number of reinforcements given, the nature and amount of the reinforcin agent, and the delay in reinforcement.

The fundamental formula linking performance an habit introduces the concept of drive which acts a a multiplicative variable according to the followin formula:

$${}_SE_R = {}_SH_R \times D$$

Further concepts are necessary to make this formul applicable to the majority of experimental studies In particular, we must add the concepts of reactiv inhibition (I_R) and of conditioned inhibition (${}_SI_R$). According to the theory, all learning, that is, al formation of stimulus–response connexions, produce some degree of inhibition or fatigue in the mediatin structures; this fatigue acts as a negative drive and tends to dissipate with time during periods of rest. Such dissipation acts as a reinforcement for the prevailing state of affairs, namely, the state of rest, so that we obtain a concept of conditioned inhibition which is essentially a negative habit, that is, a habit of not responding to the stimulus.

There is strong evidence to support this type of analysis, and the fact that many predictions can be made from the general theory, which can be experimentally verified, has led to its adoption by large numbers of students of the theory of learning. One such prediction was discussed in some detail, namely, that linking the predominance of inhibitory potential with extraverted and hysterical-psychopathic personality types, while linking the predominance of excitatory potential with introverted, anxious, depressive personality types. Experimental evidence from conditioning and other studies employed bears out this linkage.

METEOROLOGICAL RESEARCH AT PORTON

By Dr. F. PASQUILL

Meteorological Office and Chemical Defence Experimental Establishment, Porton

FROM its beginnings in 1921, research in meteorology at Porton has been primarily concerned with the study of atmospheric diffusion, and the current programme of observations, which was formally incorporated in the research programme of the Meteorological Research Committee of the Air Ministry early in 1955, involves no departure from tradition in any fundamental sense. It does, however, contain new items which significantly reflect the broadening of interest from small-scale processes such as those involved in smoke screening, to larger-scale processes such as those which determine the dissemination of 'cloud-seeding' agents from generators operated on the ground.

In considering the new lines of investigation, it will be useful first to note briefly the position reached in the earlier work. Shortly after the end of the Second World War, the now well-known pre-war studies of eddy motion and diffusion in the atmosphere near the ground were consolidated and extended, and it is especially noteworthy that by appealing ultimately to the experimentally established laws for the drag exerted by a rough surface on fluid motion over it, the *vertical* diffusion of airborne matter was quite accurately related to the observed vertical profile of wind speed over the particular surface. This important result has two limitations, first, in being restricted to the height-range over which the horizontal turbulent shearing stress may be assumed constant (usually taken to be of the order of 100 ft.), and secondly, in being applicable only in the absence of buoyancy effects, that is, in the absence of marked temperature gradients which so frequently occur vertically in the lower atmosphere. Some extension to these conditions was attempted on the basis of the observed diminution of the influence of buoyancy as the boundary is approached; but the device has only been partially justified in unstable conditions and it appears not to be acceptable at all in stable conditions. No really satisfactory progress has recently been made in the case of *horizontal* diffusion, and for the time being reliance must continue to be placed on some form of analogy with vertical diffusion.

The point to be emphasized at the present stage is that, although it is not uncommon for the prevous results to be extrapolated, there is nothing in the observations and the theoretical understanding which justifies this procedure beyond about 1,000 yd. in distance and 100 ft. in height. It is clear, therefore, that the first requirement imposed by the present extension of interest is for the accumulation of reliable observational data on the distribution of airborne material at distances of at least tens of miles from a known source. It is also necessary to examine the eddy structure which leads to this distribution; and since experience quickly shows that in tens of miles material released at the ground may diffuse vertically to thousands of feet, this examination must accordingly be made at heights considerably greater than those usually adequate in micrometeorological investigations. These last few features determine the form of the new experimental studies which are at present being carried out at Porton by the Meteorological Office in conjunction with the Ministry of Supply.

Observations of the distribution of airborne material at 'medium' range from a point source are being made with the aid of a tracer technique originally developed in the United States. A fluorescent pigment, zinc cadmium sulphide, is dispensed into the atmosphere at a controlled rate of the order of 100 gm. per min., and samples of the particles, which are mainly in the size-range 1–5 microns in diameter, are afterwards collected by drawing air through an impactor which contains an adhesive receiving surface on a drum. This drum may be rotated by small amounts at predetermined intervals, so that over a period of time a large number of separate samples may be stored on a single drum. Under ultra-violet light, the particles fluoresce with a characteristic yellow-orange colour and so may be distinguished from naturally occurring fluorescent substances and counted with confidence. As 1 gm. of the pigment disperses into something like 10^{10} particles, it can be seen that the method is remarkably sensitive.

In practice, the impactor is carried across the plume of particles by an aircraft operating at various heights in succession, or by a motor-vehicle travelling along conveniently situated roads. In this way the distribution in a cross-wind section of the cloud is obtained at various distances. Preliminary experiments during the first part of 1955 provided encouraging experience in using the technique at distances up to 40 miles and heights up to 4,000 ft., and at the same time gave a useful rough indication of the distributions to be expected in point-source clouds in certain conditions. The plan is now to conduct the experiments systematically in a number of well-defined synoptic conditions. The experiments are quite difficult operationally, requiring to start with a coincidence of predictable suitable weather conditions and the availability of an aircraft. They also bring new technical problems, such as the quantitative sampling of an aerosol cloud at the high speed of an aircraft and—a problem now receiving attention—the collection of samples in the presence of a cloud of water droplets, when the usual impactor technique becomes unsuitable. Also it is clear that the diffusive properties which are being examined exhibit a great degree of inhomogeneity, and can be described adequately only in a statistical sense from a large number of experiments. For such reasons the progress in this investigation will probably be slow.

The study of eddy structure and its effect on diffusion may be made along two lines: first in terms of the eddy velocities and their variation in space and time, and secondly in terms of the statistical behaviour of identifiable particles which may be assumed to follow the local air movement. The second line is, of course, being followed in the tracer experiments just referred to; but it is exploited there only in a broad fashion, and the resulting knowledge of the final distribution in a field of turbulence which frequently varies in space and time may itself be of limited value. It seems most necessary to support these observations with more penetrating experiments on the diffusion of particles; and for the design of these experiments and the provision of a framework to hold the results the most encouraging prospect seems to be offered by the statistical theories of turbulence. These theories recognize two ways of describing the diffusive motion of particles, one referring to the statistical displacement of a single particle with respect to its origin, and the other to the separation of a pair of particles with respect to some initial separation. There are important fundamental issues involved in distinguishing between these two systems of description; but the choice is usually affected to some extent by convenience in interpreting the observations in a practical sense and to a large extent by the feasibility of the experiments which would be appropriate. On these grounds choice has initially fallen on the former system, though experiments involving the latter system are now under consideration.

A good deal may be gained by designing the experiments on dispersion of particles for sites well above the surface, for then not only is attention directly paid to the higher levels, which must control diffusion ultimately, but also the avoidance of the marked shear in the airflow near the surface should ensure a simpler form of diffusion more amenable to treatment by theories which for tractability require the assumption of steady homogeneous turbulence. The present experiments have accordingly been planned to use dispersing and collecting equipment carried on the cables of tethered balloons, and for obvious reasons vertical diffusion rather than horizontal is investigated. Unfortunately, the conventional filtering or impacting equipment normally used for collecting particles is far too elaborate and heavy for extensive use in this fashion. This difficulty has been overcome by merely allowing the particles to impact naturally on adhesive cylinders held into the wind by light vanes spaced out along the balloon cable. Spores of *Lycopodium* are used as these are big enough (30 micron diameter) to impact with reasonable efficiency (near 50 per cent in normal wind speeds for a cylinder of diameter 0·25 in.), relatively easy to recognize and count under a microscope of moderate magnification, and yet possess a free falling velocity (2 cm./sec.) which will normally be much less than one-tenth of the vertical eddy velocities.

A first series of experiments has been carried out using the above technique, the particles being released for half an hour at a time at a height of 500 ft. and sampled at distances of a few hundred yards downwind. At the same time the fluctuating inclination of the wind at the position of release of the particles was measured by a light responsive vane, the movements of which were recorded electrically at ground-level. This instrument was designed especially for use on a balloon cable and includes automatic compensation for the varying inclination of the cable. The few results analysed so far indicate that even after a travel of 500 metres, the vertical distribution of particles may still be very closely in accordance with the distribution of the inclination of the wind. This implies the existence of a Lagrangian type of correlation, that is, one which is concerned with the velocities of the same sample of air at successive intervals of time, with a coefficient maintained close to unity for as long as one minute or more. On the other hand, from the 'instantaneous' values of wind inclination, it was found that the Eulerian correlation coefficient, namely, that between the inclination at a fixed point at a given time and the inclination at the same point some time later, had fallen to near zero in about 10 sec. This much greater persistence of velocity in a Lagrangian than in a Eulerian sense is a known feature of wind-tunnel turbulence, and evidence is now accumulating for a similar feature in atmospheric turbulence. If it is confirmed, this would mean that the convenient substitution of the measurable Eulerian coefficient for the almost unmeasurable Lagrangian coefficient is unacceptable even as a rough approximation. However, experiments of the present type may then reveal systematic connexions between the Lagrangian and Eulerian characteristics, as in fact has already been done in wind-tunnel experiments, and so provide some real physical insight into the fundamental features of atmospheric diffusion.

In addition to studying the relation between diffusion and the measurable aspects of eddy structure, it will also be important to have a more general description of the space-time variations of eddy structure than is available from the conventional micrometeorological investigations near the surface. The instrument for measuring the fluctuations of wind inclination from a mounting on a balloon cable has already been operated with some success at heights up to 5,000 ft. and has provided some interesting indications of the variations of turbulence with height and time. Plans are now in hand to increase the instrumental equipment and to use it more extensively. Such measurements should provide further knowledge of the nature, growth and decay of mechanical turbulence and convective motion over a substantial depth of the troposphere.

REVISION OF THE POLICY ON BREAD IN GREAT BRITAIN

TOWARDS the end of the Second World War, consideration was given in Britain to the desirability of specifying the type of flour to be used for bread-making once the period of war-time restrictions was over. The Conference on the Post-War Loaf[1] recommended that an 80 per cent extraction-level should be the minimum permitted and that more refined flours enriched with two or three nutrients should not be considered equally acceptable. A report by the panel on Composition and Nutritive Value of Flour has now been published* which, while agreeing that a plain flour of less than 80 per cent extraction would constitute a nutritional hazard, nevertheless concludes that the addition of thiamine, nicotinic acid and iron would provide sufficient safeguard. This is the point of view favoured by the millers, and it was chiefly pressure from them that caused the present Panel to be set up.

When, in 1953, the Government found it possible to relax controls on cereals, the trade obtained permission to prepare flour of 70 per cent extraction provided thiamine, nicotinic acid and iron were added to it ; but such flour did not qualify for subsidy when used in bread-making. To the surprise of the millers, the public showed remarkably little interest in this new flour, and sales of bread made from it never reached a higher proportion than 4·4 per cent of total bread sales ; by the middle of 1955 this proportion had dropped to 0·8 per cent. The millers claim that the public really prefers such bread but cannot afford to buy it. It would seem equally arguable that people were quite satisfied with the National loaf.

In pressing for permission to mill a low-extraction flour, the millers also sought (and obtained) permission to make up National flour by blending as well as by the straight-run process. This completely undermined the safeguards which the Conference on the Post-War Loaf sought to provide, and the value of National flour steadily deteriorated. The present report refers to "the acknowledged infringement of the spirit of the Flour Order" and states that "The Panel believes that the immediate drop in the vitamin B_1 and nicotinic acid content of National flour after decontrol and the continuing fall since, have resulted primarily from deliberate disregard of the intention of the Flour Order rather than from such factors as variations in the character of the wheat from which the flour was milled, although these factors may have played a secondary role". The report argues that a policy of adding specified nutrients would give greater assurance of their presence, since "if the miller is free to sell enriched white flour of any technical quality which he desired

---

* Report of the Panel on Composition and Nutritive Value of Flour. Pp. vii+34. (Cmd. 9757) (London: H.M.S.O.) 1s. 6d. net.

Table 1. NUTRIENTS PRESENT IN WHEAT FLOUR (REPRESENTATIVE VALUES)

Nutrients (per 100 gm. flour)	Wholemeal	Flour of 70 per cent extraction
Proteins (gm.)	12·2	11·0
Fat (gm.)	2·3	1·1
Calcium (mgm.)	45	18
Potassium (mgm.)	376	144
Magnesium (mgm.)	127	24
Phosphorus (mgm.)	287	102
Sulphur (mgm.)	165	108
Chlorine (mgm.)	62	53
Iron (mgm.)	4·2	0·8
Copper (mgm.)	0·8	0·2
Manganese (mgm.)	4·5	0·4
Tocopherol (μgm.)	910	30
Thiamine (μgm.)	500	70
Riboflavin (μgm.)	100	35
Pyridoxine (μgm.)	460	220
Choline (mgm.)	90	50
Folic acid (μgm.)	50	12
Biotin (μgm.)	8	0·5
Nicotinic acid (mgm.)	7	1·2
Pantothenic acid (mgm.)	1·3	0·6

A full set of values is not available for flour of 80 per cent extraction, but in general the higher the extraction-rate the greater the retention

there would not appear to be much temptation to add less than the specified quantities of nutrients".

The recommendations of the Conference on the Post-War Loaf, however, were intended to safeguard health by assuring that the flour used for bread-making contained not only thiamine, nicotinic acid and iron, but also a fair measure of the numerous other nutrients which wheat can supply. Since exact requirements for many of these other nutrients have not yet been established, it cannot be said for certain that the differences between 80 per cent flour and enriched 70 per cent would prove of nutritional significance, but equally it cannot be said that they would not. The matter still awaits investigation (the so-called 70 per cent extraction flour used in the much discussed Widdowson and McCance experiments[2] contained thiamine, riboflavin and nicotinic acid in quantities greater than is usual at that level and must be assumed to have provided more of the remaining nutrients also). Table 1 sets out some of the nutrients which are present in wheat and shows what a severe reduction occurs in milling to a 70 per cent extraction level. Only a few of these nutrients were given consideration by the Panel, yet the others may be of equal—or even greater—importance.

In this report the Panel gives the warning that "The history of nutrition reveals many instances where the refinement or over-purification of food has led to ill-health and there is no reason to believe that this chapter of knowledge is closed". The Panel, however, seems to assume that the National Food Survey would give adequate warning of any need for further revision of bread policy. But research workers already feel[3] that over-sophistication of food may provide the explanation of many of the diseases which beset 'civilized' man despite his extensive medical services, and the present time seems inauspicious for a reduction of the dietary supply of some fifteen or more minor nutrients merely to suit trade interests. Moreover, the proposed change would require nearly a quarter of a million extra tons of wheat a year.

NATIONAL PHYSICAL LABORATORY

OPEN DAY

'OPEN Day' at the National Physical Laboratory, Teddington, serves a dual function: it gives representatives of industry, universities, government departments and the technical and daily Press an insight into the work of one of the largest national research laboratories in Britain and, no less useful, serves to indicate the direction of national research effort in many branches of science and engineering. About three thousand visitors attended this year and 225 exhibits were on view. During the afternoon, the General Board of the Laboratory met to consider the Executive Committee's annual report[1].

The Metallurgy Division celebrates this year its fiftieth anniversary, and it was appropriate that its exhibits provided evidence of its continued interest in the constitution and structure of metals and alloys in relation to their physical and mechanical properties, work for which the Division has gained an international reputation. An investigation of the constitution of a uranium–palladium system undertaken for the Atomic Energy Research Establishment revealed the interesting feature of a considerable solid solubility of uranium in palladium; since the electronic structure of palladium is known, measurement of certain physical properties such as electrical resistivity, paramagnetic susceptibility, thermoelectric power and lattice parameter suggested that uranium dissolves in dilute solution with an effective valency of 6, but at higher concentrations the valency is probably 4.

The study of high-purity iron with particular reference to elucidating the embrittling effect of traces of impurities in amounts as low as 0·001 per cent has led to the development of an electrolytic process with the view of producing sulphur-free iron; a commercial cation exchange membrane was used for dividing the electrolytic cell and preventing the transfer of the sulphur-containing anions. Tensile tests on single crystals of iron at −196° C. indicated that orientation had a marked effect on brittle fracture[2], and further investigations of rolled Swedish iron bar using the National Physical Laboratory X-ray diffractometer confirmed that texture had a marked effect on brittle properties. The tracer laboratory is now in full operation, and equipment has been designed to measure the rate of diffusion of antimony in copper, and to study the self-diffusion of silver under fatigue stress.

The steadily increasing use of radioactive materials has necessitated a simplified calibration procedure for checking their activities. For this purpose and to ease the demand on standard samples of radioactive substances, the National Physical Laboratory's Advisory Committee on Radioactive Standards and the Atomic Energy Research Establishment, Harwell, have jointly arranged for the commercial production of a combined beta–gamma ionization chamber for the measurement of β-ray and γ-ray sources in the range 1 microcurie to a few millicuries. This equipment was shown in the Physics Division, which also demonstrated the principle of a possible alternative to the fundamental method of determining temperature by the so-called 'gas thermometer'. In this case use was made of the fact that the spontaneous fluctuations in voltage in a metallic conductor, or 'Johnson noise', have a statistical variance which is proportional to the absolute temperature; modern electronic amplifiers have made it possible to measure with the required precision the electrical energy generated, which at the melting point of gold is about a hundred-millionth of a microwatt. Such a method will be useful in permitting the absolute measurement of temperature in circumstances where a gas thermometer could not be used.

Work in the field of high-pressure physics includes the establishment of standards for the measurement of high pressures up to 3,000 atmospheres and beyond. The new National Physical Laboratory 'similarity' method for the precise calibration of pressure balances[3] was demonstrated and indicated how the hitherto limiting factor of accuracy, namely, the difficulty of measuring the effective area of piston–cylinder assemblies due to distortion, was overcome by using two assemblies of the same dimension but made in materials (hard tool steel and high tensile bronze) having different elastic constants. This Division also showed the results of tests and equipment used for determining the effective biaxial mean stress on fatigue failure, a problem of considerable importance in aircraft design; the biaxial stressing is obtained by applying gas or oil pressure to a hollow test-piece, and the results confirmed that the energy needed to propagate fast fracture is that resident in the compressed gas. Among other interesting exhibits was an ultrasonic viscometer using the National Physical Laboratory split-tube type of barium titanate torsional transducer which, in a high-intensity form, can be made capable of measuring the effects of large particles in hydrosols; and new equipment for investigating thermal and electrical conductivities to well above 1,000° C.

A notable event in the standards field was the completion in the Electricity Division of a cæsium atomic beam standard of frequency and time interval. The cæsium beam chamber on view incorporated a number of changes suggested by investigations of its performance during the past eight months[4]. The present experimental model provides a unit of time which is accurate to ± 3 in 10^{10} (one-hundredth of a second in one year). By comparison with this primary reference standard, quartz clocks, still the most convenient working standard, can now be calibrated over a period less than one second with a precision of one part in 10^9. This improved accuracy in calibration will be made generally available by the *MSF* standard frequency transmissions which are continuously monitored at the Laboratory.

In the High-Voltage Laboratory of this Division equipment is being set up to investigate the breakdown strength of a wide range of organic liquid dielectrics. It will allow the measurement at atmospheric or reduced pressure, at ambient or higher temperatures, after fractional distillation, fine filtration, drying and degassing, or any combination of these; the effect of the shape and duration of the voltage wave, as well as electrode material, will also be investigated. At the rear of this building a new million-volt 700-kVA. oil-immersed transformer is being installed to replace the bank of air-insulated transformers which have given useful service over the past thirty years. Supporting towers, and rain-spray equipment will also be provided for outdoor power-frequency tests.

A number of exhibits indicated the valuable assistance that the Divisions can give to each other in the course of their work. A good example is the new techniques used by the Metrology Division in the preparation of fused quartz cylinders for the construction in the Electricity Division of a new primary standard of inductance, from which the ohm is derived. With the aid of special lapping blocks, the variations in effective diameter of the helix have been reduced from 15μ to 5μ.

The Metrology Division also showed, in its final form, a microwave interferometer, the only equipment of its kind in existence, for the precise determination of the free-space vacuum velocity of electromagnetic waves. The fairly recent introduction of the geodimeter, which uses the speed of light for measuring distances of the order of 10 km., emphasizes the need for a value accurate to at least one part in a million. This interferometer uses two opposing microwave transmitters fed from a common source and, between them, a movable carriage supporting two receiving apertures, each facing a transmitter. The received signals are mixed to produce interference, and an accurately measured bar, two metres long, is used for determining the displacement corresponding to about 1,000 half-waves with great precision; the operating frequency is high (72 kMc./s.), and is measured by comparison with high harmonics of a quartz-crystal frequency standard.

The close contact which this Division maintains with industry was evident in the two methods demonstrated for measuring the camber of large rolls, one using an autocollimator and the other an interferometric technique. A number of exhibits, demonstrating the application of pneumatic gauging, were of special interest. The thickness of thin sheet material was shown being measured continuously by this method as it passed over a roller beneath a number of air jets. This apparatus, as at present designed, will measure to a lower thickness limit of 0·002 in. and an accuracy of ±·1 per cent. By means of a selector switch, variation in thickness of the sheet beneath any one of the jets can be continuously plotted by a pen recorder. A similar technique was demonstrated for testing the flatness of unexposed photographic plates.

Two thin-film type bolometers are being developed in the Light Division to meet the industrial need for sensitive non-selective detectors of infra-red radiation. Thin films of gold or antimony, less than two-millionths of an inch thick, supported on a plastic pellicle, are used. The blackened gold film bolometer is quite as effective as the best thermal detectors at present available and is robust enough for monochromators used in chemical process control; the amorphous antimony bolometer also shows promise in that it is highly sensitive to voltage and has an impedance so large that it can be connected directly to a valve amplifier, thus saving the expense of a step-up transformer.

Among other interesting exhibits in this Division were a photo-electric polarimeter which was contructed to investigate inaccuracies in the calibration of quartz plates used as standards of optical rotation ; and a gas refractometer developed for testing trichloroethylene inhalers, with which the oncentration of trichloroethylene in air is determined y comparing the refractive index of the vapour mixture with that of air in a Jamin-type interferometer. New methods have been developed for producing replica diffraction gratings in plastic ; hey make it possible to join several lengths to form ontinuous accurate gratings several feet in length. t was shown how these gratings can be used for the accurate measurement of movement or displacement by counting the moiré fringes produced when a short ndex grating is moved over a length of fixed grating of the same pitch. The possibilities of this technique of indicating position is being actively investigated and has been adopted in one instance for the automatic control of machine tools.

Work on the design of electronic digital computers continues in the Control Mechanisms and Electronics Division, which exhibited units of the new Automatic Computing Engine (ACE), that was seen in the process of construction. This will be a more powerful tool than its predecessors, the ACE Pilot Model and its engineered version DEUCE, as made by the English Electric Co., Ltd. The new computer will have a larger storage capacity or 'memory' and have an overall speed four times greater than DEUCE ; n a typical working day it will average 20,000 'three address' operations per second and its mercury delay ines and magnetic drums will store a total of $1\frac{1}{2}$ million binary digits. With its other special facilities this machine will allow the solution of very complex problems which have hitherto not been possible with existing computers. A simplified flow diagram for wage accounting directed attention to the possible use of a high-speed computer, with magnetic tape equipment, in office work. This was based on the work done for a study group formed in 1954, consisting of representatives of the Organization and Methods Division of the Treasury, the Ministry of Pensions and National Insurance and the National Physical Laboratory, the first report of which has ust been published[5]. This Division is also concentrating on the design of data-processing equipment and exhibited an automatic graph-plotter which enables information in punched card form to be plotted automatically at a rate of one point every two seconds for points lying fairly close together. Information is read from the cards serially and supplied through a relay distributor to the relay stores, the outputs of which are voltages proportional to the number held ; these voltages are then supplied to the plotting table, which traverses the carriage to the corresponding point, and the plotting head is operated.

The Mathematics Division is now using DEUCE for solving large-scale numerical calculations arising n scientific research and industrial design. This machine was seen in operation and is being used for solving problems in mathematical physics, linear algebra, ballistics and aircraft flutter.

The facilities of the Ship Division are being extended, and a model was shown of the new Ship Hydrodynamics Laboratory now being built at Feltham, Middlesex. This will provide a ship model-testing tank 1,300 ft. in length, 45 ft. wide and 25 ft. deep, and its carriage will have a maximum speed of 50 ft. per sec. There will also be a new water tunnel 40 in. in diameter for research on propellers ; work on 'cavitation' will be facilitated by a resorber circuit which will go 200 ft. below ground-level. A problem associated with the arrangement for supporting and driving the propeller model in this new water tunnel was demonstrated. A mechanical model indicated the method of investigating the different modes of whirling of an overhung shaft and the effects of alteration in the shafting or bearings at critical whirling speeds, with the view of determining the best supporting system. In the Yarrow Tank a lightship was seen undergoing tests in rough water. These experiments are on behalf of the Corporation of Trinity House and the Commissioners of the Port of Calcutta, and are being made under conditions simulating the effect of tide, wind and waves on the riding behaviour of an anchored lightship. The high cable tensions are affected by the hull form, and methods of reducing the cable tension have been suggested.

Of special interest to visitors to the Aerodynamics Division were the wind tunnel exhibits demonstrating methods for improving the efficiency of lifting surfaces by preventing flow separation. Such studies are of vital importance for improving the landing and take-off performance of high-speed civil and military aircraft, where the trend towards highly swept wing-forms has necessitated relatively high landing and take-off speeds. High lift was demonstrated in the 13 ft. × 9 ft. wind tunnel by blowing high-velocity air over a trailing-edge flap of a half-model delta wing to re-energize the boundary layer. In the 9 ft. × 7 ft. wind tunnel experiments were in progress to ascertain the usefulness of boundary-layer control at the wing nose when combined with jet flaps at the wing trailing-edge.

In high-speed flight, shock-induced boundary layer separation from a wing or other component of an aircraft seriously affects stability and control of the aircraft. This formed the subject of a film, in colour, which was shown to visitors. An interesting exhibit concerned experiments on a thin half-aerofoil section designed to be free from boundary-layer separation for an appreciable range of lift coefficients at all speeds, thus enabling the formation of a shock wave to be studied independently of boundary-layer interaction and a check to be made on theoretical results. The influence of the shape of the leading edge on change in the type of separation that occurs as the Mach number is raised for a wing at high incidence was also being studied.

Equipment specially designed for the measurement of aerodynamic forces on oscillating wings was exhibited in this Division. It is intended to provide fundamental data relating to oscillating forces at high speeds and frequencies, and will be used for checking the theoretical methods at present used when designing aircraft to guard against oscillatory instability in flight. An electro-mechanical feed-back system is used, incorporating a torsion bar linking two inertias, one carrying the model and a displacement pickup, and the other being electromagnetically excited at its natural frequency.

The Laboratory's testing facilities are constantly being extended to meet new demands. Three new water-baths have been installed in the Test House to facilitate testing and avoid fatigue of observers testing clinical thermometers, of which more than half a million were tested last year. With the increasing use of viscometers in various industrial applications, and by the oil industry in particular, there has been an increasing demand for the calibration of a range and variety of these instruments ;

temperature control has been installed in rooms used for this work. The testing of trichloroethylene inhalers intended for use by registered midwives has been facilitated by the use of the new gas refractometer referred to previously. Two prototypes have been approved, and about 110 inhalers have been tested. 'Trouble-shooting', the theme of an interesting exhibit, stressed the assistance given by the Test House to enable manufacturers to overcome their production difficulties and to improve the quality and accuracy of their output.

OBITUARIES

Prof. Carl Ramsauer

Carl Ramsauer, who died in Berlin on December 24, 1955, was an outstanding character as well as an outstanding physicist. As a young man, he made his way by his toughness and purpose. Born on February 6, 1879, in Osterburg, a little place in Oldenburg where his father was the Lutheran parson, in his early twenties he occupied a diversity of positions, including those of schoolmaster and assistant in the torpedo laboratory at Kiel, at which University he took his doctorate with an interesting and original thesis on the mechanism of ricochet from water. He was twenty-eight when Lenard, who had been professor at Kiel, enabled him to take up an academic career by appointing him to a post in the Physics Institute at Heidelberg. Here he worked, except for the war period, during which he was an artillery officer, until 1921, when he was appointed professor of physics at the Technische Hochschule at Danzig. With Lenard he carried out a series of significant researches on the ionization produced by ultra-violet light; but the work that brought his name into prominence was his discovery, in 1921, that slow electrons pass much more easily than swifter ones through the atoms of the rare gases, the so-called Ramsauer effect. In this connexion he introduced the term Wirkungsquerschnitt (effective cross-section), which has been so widely used.

At Danzig, Ramsauer proceeded to transform the small and comparatively unimportant department into a first-class institute for teaching and research in physics. He was by inclination and training an outstanding teacher, taking the greatest pains and pleasure to devise effective lecture experiments and to make clear the fundamentals of the subject. The research school, which was occupied mainly, but by no means exclusively, with the passage of electrons through matter, was known for the precision and clarity of its work. By 1928 his reputation was such that when the Allgemeine Elektricitätsgesellschaft decided to found a research institute, Ramsauer was appointed to direct it. His gifts as an organizer and controller of research found full expression in this extremely responsible post. Under him work proceeded not only in physical, but also in chemical, electrotechnical, metallurgical and other departments of the great institute. He installed 'technical-physical workshops', which were of great value. He continued his personal research on effective atomic and molecular cross-sections, and the work which he carried out with Kollath on the scattering of protons is classical. In 1931 he became joint editor of the *Zeitschrift für technische Physik*, and many other responsibilities of this nature accrued to him.

During the Second World War, Ramsauer was elected president of the Deutsche Physikalische Gesellschaft, a very difficult position at that time With characteristic courage he spoke out against the many abuses and shameful personalities which were ruining German physics, his letter, sent in 1942, to Rust, then Minister for Education, being particularly uncompromising. It had no result; but if Ramsauer had been a less valuable and less respected man it might have been fatal for him.

After the War, Ramsauer occupied himself with reorganizing the teaching of physics at the Technische Hochschule at Charlottenburg, a task for which his gifts and experience particularly fitted him In 1953 he published a remarkable little book dealing with the history of certain fundamental experiments in physics. He did not give up his post until he reached the age of seventy-five, and died shortly after his resignation.

Ramsauer was a quite exceptional personality. He disliked any parade of sentiment, but he was a staunch friend and a man of firm principles, who never truckled to those in power. He was a most entertaining talker, with a strong and sometimes biting sense of humour, to which he gave epigrammatic expression. For example, of a certain somewhat undistinguished physicist who had a double name—let us call him Wolf-Braun—he said, "Gauss–Weber were two men, Mittag-Leffler was one man, Wolf-Braun was nobody". He had a close acquaintance with German university folk-lore, including the legends of Bonifacius Kiesewetter, and a great knowledge of German literature in general, including many byways. He will long be remembered by all who had to do with him, and especially by the few still living who knew him at Heidelberg.

E. N. da C. Andrade

Sir John Stirling-Maxwell, Bart., K.T.

Sir John Stirling-Maxwell died on May 30 at the age of eighty-nine at his home, Pollok House, famous for its lovely gardens, near Glasgow. He succeeded his father at the age of eleven, and went to Eton and then on to Trinity College, Cambridge. He was Conservative member of Parliament for the College Division of Glasgow between 1895 and 1906, when he lost the seat. It was then that he gave his time to his real hobby. Sir John may be termed one of the early modern pioneers of forestry, then called arboriculture in Scotland and England, in the latter part of the past century and the early years of the present. He studied the subject intensively in many European countries and made use of the knowledge so acquired on his own estate, and was always ready with advice or suggestions to friends.

In his own practice, after failures to establish sitka spruce plantations on his estate at Corrour, and his greatly loved lodge there, by the usual methods of level surface planting on peat soils, he introduced the method he had seen in Belgium of mound planting, in which the plants are placed in holes in the turves cut out in making the drains. He had immediate success at Corrour; and when, a few years later, the Forestry Commission began its work in the country, it followed Sir John on peat soils, afterwards greatly elaborating other methods. Sir John, whose whole heart was in forestry, was one of the first Commissioners, and his appointment as chairman of the Forestry Commission in 1929 was warmly hailed by foresters and all who knew of his work and his enthusiasm, and his departure at the end of his term of office at the end of 1932 was equally regretted. His quiet geniality, understanding and common sense were greatly appreciated and loved.

Sir John's life was devoted to public service. He had a great affection for art and acted in many public positions in this respect: as trustee of the Royal Fine Art Commission for Scotland, chairman of the Ancient Monuments Board of Scotland and as a trustee of the Scots National Galleries. He was an original member of the Board of Trustees of the Wallace Collections appointed to administer the bequest in 1897, and he served continuously on the Board, being its chairman for the past twenty-five years.

Sir John did a great deal to encourage the beginnings of forestry in Great Britain, and his name will remain enshrined in the annals of forestry.

E. P. Stebbing

NEWS and VIEWS

Experimental Philosophy at Oxford: The Right Hon. Viscount Cherwell, P.C., C.H., F.R.S.

For a man who shuns publicity, Lord Cherwell has been much in the news lately. In the recent Birthday Honours List he was made a Viscount and very shortly afterwards he announced his impending resignation from the Dr. Lee's chair of experimental philosophy at Oxford. F. A. Lindemann (now Viscount Cherwell) was educated in England and Germany and took his Ph.D. degree under Nernst at the University of Berlin in 1913. During his period in Germany he published, in conjunction with Nernst, a series of papers on "Studies of Specific Heats at Low Temperatures", and also proposed modifications in the Planck–Einstein formula for specific heats of solids based on the quantum theory and extended it to gases. Later, he published a book entitled "The Physical Significance of the Quantum Theory". During the First World War, Lindemann served as an experimental pilot and research scientist at the Royal Aircraft Establishment, Farnborough. It was during this period that he played a very large part in the successful solution of the spinning aircraft problem. In 1919, Lindemann was appointed professor of experimental philosophy at Oxford, so that he has held this chair for thirty-seven years. During this period he has built up the Clarendon Laboratory and initiated many important researches to such effect that to-day the Clarendon Laboratory is among the best equipped and staffed laboratories in the world for both low temperature and nuclear research work.

In pre-war years Lindemann formed a very firm friendship with Winston Churchill, and when at the outbreak of the War the latter was appointed First Lord of the Admiralty, Lindemann joined him in the capacity of personal scientific adviser. Later, when Churchill became Prime Minister, he moved with him to Downing Street. He was raised to the Peerage as Lord Cherwell in 1941 and in 1942 became Paymaster General and a member of the Cabinet. His duties were primarily scientific and statistical, and he was charged with the responsibility of keeping the Prime Minister acquainted with all the scientific problems and developments which affected the war effort. This he did largely by the use of his characteristically simple but illuminating methods of presenting information. In addition to this, he also accompanied the Prime Minister to the historic Quebec and Potsdam Conferences. Cherwell again became Paymaster General in 1951 and served in a similar capacity. His particular interests at this period were in the atomic energy field, and he was one of the main protagonists of the plan afterwards adopted for the removal of the Atomic Energy programme from the Civil Service. After his return to Oxford in 1953 he continued to serve as a member of the new Atomic Energy Authority. Cherwell is a man of strong opinions which he has not hesitated to advance. Many people have disagreed with him, but few will deny that he has had an important influence on our time.

Sir Francis Simon, C.B.E., F.R.S.

Sir Francis Simon, professor of thermodynamics in the University, has been appointed to succeed Viscount Cherwell. The Clarendon Laboratory will thus have as its new head a man who has a world-wide reputation for his achievements in all branches of low-temperature physics. Sir Francis, like Lord Cherwell, began his scientific career under Nernst, and it is not surprising that much of his earlier work was connected with the Nernst heat theorem. Indeed, the fact that this theorem is now generally recognized as the third fundamental law of thermodynamics is largely due to his work. During this period in Germany he also devised the small-scale cryogenic techniques, in particular the expansion method for liquefying helium, which made it possible to conduct low-temperature work even in laboratories with only quite modest facilities. On leaving Germany in 1933, he went to the Clarendon Laboratory at the invitation of Prof. Lindemann and became reader and later professor of thermodynamics. Under him the low-temperature department of the Clarendon Laboratory has grown to be one of the leading cryogenic laboratories of the world. His many interests have included the properties of liquid helium, magnetic cooling, low-temperature specific heats (in particular, the study of internal transitions), nuclear orientation, thermal conductivities and the properties of solids and fluids at high pressures and low temperatures. During the War, Prof. Simon played an important part in the British Atomic Energy project. He was one of the first to see the feasibility of a diffusion plant for the separation of the uranium isotopes on an industrial scale and he had a large group working under him on this project. Since the War he has also turned his attention to many questions of scientific policy, and he is well known for his views on fuel policy, on scientific and technological education, and on the correct use of scientific man-power.

Chemistry at Birmingham : Prof. M. Stacey, F.R.S.

Prof. M. Stacey, who succeeds Prof. H. W. Melville (see *Nature* of February 11, p. 260) at the end of the present academic year as Mason professor of chemistry in the University of Birmingham, is the most outstanding Birmingham graduate of his time. He graduated under the late Sir Norman Haworth and continued, with short breaks in London and in the United States, at Birmingham as research student, lecturer, reader, until in 1946 a special chair was created for him to give him further scope for all his activities. Since that time he has expanded enormously the organic work at Birmingham. For many years under Haworth, Birmingham was the centre for carbohydrate chemistry in Great Britain, and the great advances made in this period laid the foundations of much of the subsequent developments into wider fields. Stacey's work was interrupted by the Second World War; but under the auspices of the Tube Alloys' project in Britain, he became interested in the chemistry of uranium and also of fluorine. This gave him the opportunity to enter the field of the organic chemistry of fluorine compounds and this part of his activities has flourished just as much as the carbohydrate field; at various academic institutions in Britain he has developed unique methods of dealing with the synthesis of a great variety of fluorine compounds and in seeking new uses for them in every possible way. Under Stacey's leadership, organic chemistry has increasingly widened its scope in Birmingham, with emphasis, too, on the biological implications of these developments of organic chemistry. In all these developments full use has been made of the more specialized techniques that have been available in the laboratory, especially on the physical side. These have made progress possible which was undreamt of in pre-war years. With greater responsibilities, the Chemistry Department under Stacey's guidance will, without doubt, develop actively and broadly in the years to come.

Italian Honours for Sir Cyril Hinshelwood and Prof. E. B. Chain

On June 5, the Italian Foreign Minister honoured two British men of science, Sir Cyril Hinshelwood, president of the Royal Society, and Prof. E. B. Chain, by bestowing on them the order of the Grande Ufficiale al Merito della Repubblica, one of the highest civil distinctions in Italy. Sir Cyril Hinshelwood has been a frequent visitor to Italy, and his work and personality are greatly appreciated in this country, the language of which he has mastered with perfection. He has done much to strengthen the ties between British and Italian scientists. Prof. Chain, formerly of the University of Oxford, has worked since 1949 in Rome, where he has built up a large and very active department for biochemical research at the Istituto Superiore di Sanità, the chief centre for medical research in Italy.

Expansion of Metallurgy at Oxford

At a meeting of Congregation on June 12, a statute was promulgated which added the science of metals to the list of subjects that may be offered at Oxford in the Honour School of Natural Science. This subject covers much of the ground that is covered by those who offer chemistry in that Honour School. The amount of organic chemistry, however, has been reduced in order to provide room for the science of metals. The new course is divided into Parts I and II on the same lines as the chemistry course, and in Part II a candidate will submit a thesis on a metallurgical subject after spending a year on research. Classified honours will be awarded on the combined results of both parts.

The new course marks a further stage in the development of metallurgy at Oxford which follows the establishment of the George Kelley readership by the Pressed Steel Co. and the appeal for funds for the subject which was strongly supported by the late chairman of the Company, Major Albert Pam. Post-graduate research work in metallurgy has been carried out at Oxford for more than thirty years under Dr. W. Hume-Rothery in the Inorganic Chemistry Laboratory, where its development owes much to the interest of Sir Cyril Hinshelwood. An independent Department of Metallurgy under Dr. Hume-Rothery is now being set up in temporary accommodation, and it is hoped that a new laboratory will be built in the next few years. The new development is particularly welcome in view of the close association of Oxford with metal-using industries.

National Parks Commission

There are now eight national parks in Britain—the Lake District, the Peak District, Snowdonia, Dartmoor, the Pembrokeshire Coast, the North York Moors, the Yorkshire Dales and Exmoor, with a total area of 4,333 square miles—while two further areas have been designated as national parks—Northumberland and the Brecon Beacons. One of the duties of the National Parks Commission is to bring to the notice of the public the setting up of these parks and to explain why they have been set up. There is still much misunderstanding among the general public, and the Commission takes every opportunity to show that the designation of an area as a national park effects no change in the ownership of land. The land is not 'nationalized' nor does designation as a national park confer on the public any right of access. Users of national parks are asked to respect privately owned country inside the parks in the same way that they would outside. They are also asked to observe the "Country Code", a code of behaviour for visitors which has been set out in an attractive booklet by the Commission and which can be obtained from H.M. Stationery Office, price 4*d*.

Museum of English Rural Life, Reading

The first annual report of the Museum of English Rural Life at Reading, although dated 1955, covers the first four years of the existence of this rapidly growing institution. This Museum had the great advantage of starting from scratch and thus was able to determine its policy and administration, both of which were based on orthodox museum practice in Great Britain. Contrary to traditional custom, however, the report, rather than being a record of month-by-month activities, includes the abbreviated text of a lecture delivered by Mr. Uldall, keeper of Frilandsmuseet, the open-air section of the National Museum of Denmark. This lecture details some of the principles which are now slowly emerging concerning folk museums and folk parks and stresses the fact that the material acquired should be regarded primarily as objects for the basis of scientific study rather than exhibition pieces.

Beauty and Order

A FINELY illustrated article by Dr. P. Weiss in a recent issue of the *Scientific Monthly* (81, No. 6; December 1955) elaborates the regularity and consistency of design in living forms. The regularity is expressed in such features as symmetry, repetition and alternation of elements; and consistency, as in the use of curves, proportions, size gradients, and so forth, in subdividing space. The rule of order over randomness, of pattern over chaos, of law over accident is well brought out, while patterns in Nature are shown to be of both space and time. In the last analysis, each organic form has had its history and has come to be what it is through long sequences of developmental processes. Since all form is thus merely a momentary cross-section through a stream of formative and transformative processes, what is admired as order and beauty in the final form is only a product and an index of the measured orderliness of the developmental actions and interactions by which it has come about. Static form is only a precipitate of underlying and antecedent formative dynamics.

Population Structure in Salt-Marsh Song Sparrows

THE song sparrows (*Melospiza melodia*) that live on the salt marshes of San Francisco Bay, California, have attracted the attention of students of birds for the past sixty years. The principal reason for this has been their morphological distinctness from all other song sparrows, including those which live in areas close to the salt marshes. Such a pattern of differentiation and distribution has always raised the problem of how the salt-marsh populations maintain themselves as distinct entities. A study by Richard F. Johnston continues previous work on salt-marsh song sparrows to determine what characteristics of salt-marsh populations influence or have some relationship to the maintenance of their morphological and/or genetical integrity, and how these characteristics express themselves (*Condor*, 58, No. 1; January–February 1956). Factors influencing the initiation of breeding in the song sparrow are closely associated with the biological growing season and include the photoperiod, temperature of the preceding three months, and the amount and distribution of the winter rainfall; these also influence the amount and quality of the song sparrow's food, which may well be the most proximate factor. The inception of breeding seems not to be closely related to any 'temperature threshold' or 'warmth-sum'.

Breeding spans the period March–June; the peak of first nestings is at the end of March. This is more than two weeks earlier than in upland song sparrows at the same latitude and seems to represent an adaptation to marsh life, for the birds thus nest mainly during lower tidal conditions. It is not the absolute height of the tides that governs egg and nestling mortality, but whether or not the birds can nest early enough to escape the high run of tides in April to June; when they breed late, there is high mortality caused by the high tides. Male song sparrows set up territories during late autumn and winter and are completely territorial by late February. Territorial defence is lacking during July–September when the adults moult; autumnal territoriality is seen in mid-September. Adult birds rarely shift their territory from one breeding season to the next. Dispersal of juveniles occurs in the late spring and summer and halts in late August and September when territorial activity rises. The median distance of dispersal, hatch-site to breeding-site, for 34 song sparrows was 185 metres. The limited adult movement and restricted distance of dispersal of these song sparrows mark them as one of the most sedentary population of birds yet investigated.

Predator Control

THE *Bulletin of the International Union for the Protection of Nature* (5, No. 1; April 1956) includes an account of the effects of attempted predator control in America. On the Kaibab Plateau in north-western Arizona, an area so noted for its mule deer that it was made into a game reserve more than fifty years ago, cougars and wolves were trapped to ensure that the deer would be protected. Within a few years the deer population had increased to such an extent that pasture-land was exhausted and even the forest was damaged. As a result, thousands of deer starved because of loss of their food supply. On Valcour Island, in Lake Champlain, an investigation was carried out to test the possibility of augmenting game by means of successful predator control. This operation allowed the game, mainly ruffed grouse and hares, to increase during the first four years from a small to a moderately high level, and then the population began to decline. In the absence of predation, disease apparently became a major limiting factor. As the sick were no longer eliminated, unchecked epidemics ravaged the game which was to be protected.

A Virus Latent in Turnips

J. P. MACKINNON has reported on this phenomenon as follows (*Canad. J. Bot.*, 34, 1, 131; 1956). Green peach aphids reared on turnip stecklings acquired a virus that was transmitted to plants of *Physalis floridana* Rydb. and *P. pubescens* L., hosts used in potato leaf-roll studies. Symptoms on these hosts consisted of a yellowing of the veins of the leaves. *Nicandra physalodes* L., when infected, showed severe stunting and chlorosis. The virus was carried without symptoms on turnips and showed only slight stunting on several species of *Brassica*. It was not transmitted by mechanical inoculation, and it does not appear to be similar to any of the viruses previously reported in turnips. The aphid *Myzus persicae* (Sulzer) acquired the virus during a seven-hour feeding period, and after a latent period of approximately 23 hr., transmitted the virus during a one-hour test-feeding period. Once infective, aphids remained so for several days.

American Prairies

IT has long been held that the vast extent of grassland, which is almost treeless, extending from western Indiana to the eastern slopes of the Rocky Mountains was made by man and due to the 'fire hunting' of Indian tribes. Among many tribes, fire drives were used in the pursuit of bison and other large-game animals. Whatever their purpose, such fires ran unchecked until they reached a stream or other baulk. Repeated burning destroyed existing trees and prevented their replacement by new growth. This belief has now been challenged by an American archæologist, Dr. W. R. Wedel (Smithsonian News Release, Dec. 23). Studies of habitation sites show that there were great dust movements over the plains before there was any agriculture. The dust, he suggests, must have been picked up from dry uplands from which the grass had been killed by drought. Geological surveys also show that there were typical grassland soils in the area throughout the ice ages. They were typical of each recession of the glacier and are now buried deep under the present land surface. At present, natural tree growth is practically restricted to river-bottom lands and ravines, and there is very little tendency for the woodlands to spread out over the plains.

The Weather Service in Great Britain

A NEAT little pamphlet entitled "Your Weather Service", prepared by the Meteorological Office and Central Office of Information (revised edition; pp. 52+8 plates. London: H.M.S.O., 1955; 1s. 6d. net), describes in popular form the organization of the Meteorological Office, the making of meteorological observations, and their collection and use both in weather forecasting and in the longer-term climatological work which the Meteorological Office performs in its capacity as the public memory of the weather. The terms used in broadcast weather forecasts are defined, and maps show the areas used in the forecasts broadcast for the British Isles and the adjacent sea areas. The pamphlet gives full details of how to obtain special weather forecasts and meteorological advice, and ends with a table of the normal temperatures of each month in each of the areas used in the broadcasts and a detailed table of mean and extreme temperatures, sunshine, relative humidity, fog, thunder, snow and wind at Kew Observatory. Plates show the making of surface and upper-air observations and their collection, the plotting of them on charts, and the testing of instruments. One plate shows in diagrammatic form the very wide sphere of applications from which inquiries are received in the British Climatology Branch of the Office, ranging from "where to live" to the design of cooling towers at power stations. On the much-discussed subject of "old-fashioned summers", there is no evidence that Britain is either warmer or colder than it was a century ago. The pamphlet describes the services of reference on the spot and of lending of the Meteorological Office Library, which contains the greatest collection of meteorological literature in Britain and is one of the largest in the world. The pamphlet also gives an outline of the publications, from the Daily Weather Report to the highly specialized research series of Geophysical Memoirs prepared in the Office.

Geophysics in Pakistan

THE director of the Meteorological Service of Pakistan, Mr. S. N. Naqvi, began last year the publication of a duplicated series entitled "Geophysical Review". Part 4, "Technical Progress Review, No. 7" (September 30, 1955), describes the current state of geophysical research in Pakistan, and in particular the work in progress on atmospheric physics, geomagnetism and seismology. In cloud physics, condensation on large hygroscopic particles has been studied under the guidance of Dr. E. M. Fournier d'Albe, and trials of cloud-seeding by spraying salt particles into the air have been made. Actinometers have been brought into use and their records analysed to obtain the usual statistics of solar radiation and the 'measure of turbidity' which is the exponent of the Rayleigh transmission factor of the solar beam. The Agrimeteorological Observatory has worked on soil temperature and water content at depths up to 1 m. in an orchard in relation to the minimum water requirements of the fruit trees. The Geomagnetic Section has studied the variation of the scale values and temperature coefficient of the horizontal force magnetometer, ionospheric structure and, with a Dobson spectrometer, the variation in ozone content of the air. The Seismological Observatory has installed accelographs at Quetta and Sylhet (East Pakistan), the records of which will be valuable in the construction of buildings to resist earthquakes, and has made detailed studies of the recent larger shocks in the Dominion. Geophysical research is developing rapidly in Pakistan, and the Meteorological Service of Pakistan, one of the most recently formed such services in the British Commonwealth, is doing valuable service in publishing this record of progress up to date.

Higher Education in the United States

IN the September issue of the *Annals of the American Academy of Political and Social Science*, under the title "Higher Education under Stress", is presented a comprehensive picture of the issues confronting higher education in the United States. Three general papers, by F. J. Brown on a long-range view of higher education, by G. K. Chalmers on the purpose of learning, and by M. H. Trythen on meeting man-power needs, are followed by eight others dealing with specific issues in the United States. These are of slight interest to the British reader, with the exception of Dr. H. D. Gideonse's "Academic Freedom: a Decade of Challenge and Clarification" and Dr. H. E. Wilson's review of the role of the university in international relations; but for these two papers alone the number will be welcomed by many in Britain. The greater part of the issue is devoted to the papers presented at the Conference on Methods of Financing Higher Education, held in Philadelphia during May 20–21, 1955. For the most part they are concerned with specifically American issues which have no close counterpart elsewhere, and, while the issue forms an admirable supplement which brings up to date J. D. Millett's report on "Financing Higher Education in the United States", published in 1952, except for the papers indicated it throws little light on the problems with which the university administrator or teacher in Britain is confronted.

Education through Physics

WHAT qualities does the world expect of a well-educated man? That he should have a tough and inquiring mind, able, and indeed anxious, to tackle new problems, new situations. That he should be creative, not hidebound, independent and not relying solely on the minds of others. That he should be well informed generally and really knowledgeable about certain subjects or parts of subjects. That he should appreciate spiritual and æsthetic values. That he should be intellectually honest, able to recognize a hard fact, and not afraid to give up preconceived ideas in the face of demonstrable proof. That he should be able to express himself clearly, convincingly and concisely in writing and in speech. That he should be able to live with and collaborate with others, showing the tolerance which arises from an understanding of studies and beliefs other than his own, but not tolerance of slovenliness of any kind. That he should exhibit the qualities of perseverance and humility, and above all, of judgment. These views were put forward by Prof. F. A. Vick at a meeting of the Education Group of the Institute of Physics. Prof. Vick does not pretend that all these qualities can be acquired solely from courses in physics, although he believes that most, if not all, f them can be developed by contact with some physicists. A great deal more could be done to ducate students' minds than is sometimes done. Courses in the physical sciences could make contributions to the education of the mind which few other subjects can.

Science Masters' Association

Besides details of a wide range of activities in 1955, the annual report of the Science Masters' Association contains one item which reflects the enthusiasm and enterprise of its members. Its radioactive isotopes sub-committee has continued to nvestigate the possibility of producing experiments suitable for schools. Much research has been carried on to devise suitable and inexpensive apparatus, especially that which can be put together in the school itself. The sub-committee is particularly anxious to recommend experiments which can be done by use of radioactive isotopes only, or can be done more effectively by their use than by the conventional methods used hitherto. The sub-committee does not look with favour upon the use of fundamental particles as 'wonders' but desires to make use of them as 'tools', an adjunct to technique rather than a new body of phenomena to be added to an already over-filled syllabus. Progress in this work has been delayed because the necessary Statutory Panel demanded by the Radio-active Substances Act has not yet been set up by the appropriate Government departments. Recently steps have been taken by the Ministry of Education to form such a Panel, and publication may shortly be expected of the schedule defining the limits within which experiments in schools will be permitted.

Announcements

Prof. John F. Fulton, of the Yale University School of Medicine, has recently received an honorary doctorate of medicine of the University of Upsala.

The following appointments have been made in the University of London: Dr. W. S. Peart, senior lecturer in St. Mary's Hospital Medical School, to the University chair of medicine tenable at that School; Dr. Harry Wilman, lecturer in applied physical chemistry in the Imperial College of Science and Technology, to the University readership in applied chemical physics tenable at that College.

The sixth Parliamentary Conference on World Government will be held in the County Hall, London, during July 28–31. Further information can be obtained from the secretary-general, G. McAllister, 21 Hampstead Lane, Highgate Village, London, N.6.

The next Cytological Congress will be held at the University of St. Andrews, Scotland, during August 28–September 3, 1957. Admission will normally be restricted to members of the Society for Cell Biology and their guests. Others wishing to attend should communicate with the secretary of the Congress, Prof. H. G. Callan, Department of Natural History, The University, St. Andrews, Scotland.

The U.S. Combustion Institute will hold its sixth international symposium in Yale University during August 19–24. A large number of aspects of combustion will be discussed; but in general the purpose of the symposium is to consider new experimental results and advances in theory, as well as their application in engineering practice. Further information on the technical programme can be obtained from the Combustion Institute, 200 Alcoa Building, Pittsburgh 19, Pa. Those wishing to attend the symposium should write to the Combustion Symposium Office, Mason Laboratory, Yale University, 400 Temple Street, New Haven 11, Conn.

The British Society for Research on Ageing has planned a joint meeting with Dutch gerontologists, to be held in Amsterdam on the afternoon of July 27 and following morning. The meeting is open to all, and those attending the International Physiological Congress in Brussels, commencing on July 30, may find it convenient to attend the Amsterdam meeting *en route*. Further information can be obtained from the honorary secretary of the Society, Dr. G. H. Bourne, London Hospital Medical College, Turner Street, London, E.1.

The eighth British Mathematical Colloquium will be held in the University of St. Andrews during September 4–6. The subjects for discussion on the respective days will be algebra and the theory of numbers; analysis; and geometry and topology. As in previous years, the Colloquium is open to university academic staff, Civil servants in scientific departments and, subject to limitations of accommodation, to research students. The membership fee is 10*s*. Application for membership should be made to D. Borwein, Department of Mathematics, St. Salvator's College, St. Andrews, from whom further information can be obtained.

A joint meeting of Commissions I and II of the International Institute of Refrigeration will be held in Louvain during September 4–7. Four general topics will be discussed: methods for the detection at very low temperatures of traces of impurities in metals, semiconductors and other solids (magnetic susceptibility, electrical resistance, electronic resonance, heat conductivity, etc.); heat conductivity and viscosity coefficients of gas and liquid mixtures at low temperatures; relationship between insulating materials and the gas or vapour included; and hygrometry. Those interested in attending should write to Prof. I. van Itterbeek, Naamsestraat 73, Louvain, Belgium, from whom further information can be obtained.

A European mycological congress will be held in Brussels during September 15–22, and all persons interested in the study of higher fungi are invited to attend. This is the first such meeting, and it is proposed to repeat it at three-year intervals. The working languages will be French, English and German. Further information can be obtained from Dr. P. Heinemann, 26 Rue J. W. Wilson, Brussels. Immediately after the congress a symposium will be held in the University of Liège on the ecology of higher fungi. Those interested should write directly to Dr. F. Darimont, Institut Botanique de l'Université, 3 Rue Fusch, Liège, indicating the subjects they would like to be covered.

A fourth list of amendments to the third edition of the "World List of Scientific Publications", including amendments to library holdings after the date of publication, has been published by the Documentation Committee of the Society of Chemical Industry in *Chemistry and Industry* (1955, 1764–67). Details of any errors discovered in the "World List" should be sent to: Miss M. I. Wyatt, The Laboratories, J. Lyons and Co., Ltd., 149 Hammersmith Road, London, W.14.

BRITISH RAYON RESEARCH ASSOCIATION

OPEN DAYS

THE British Rayon Research Association held open days during May 10–11 at its laboratories at Heald Green, Wythenshawe, on the south side of Manchester. These open days are intended to be an annual event in future. Representatives of member firms, universities, technical colleges, trade associations, the Department of Scientific and Industrial Research, other research associations, scientific and technical societies, and trade unions took advantage of the invitation to inspect the Association's work. This can be divided into three main sections: fundamental research, which absorbs approximately 40 per cent of the effort; applied research, including machinery development and instrumentation, which absorbs a further 40 per cent; and member service.

The fundamental research can be briefly described as an investigation into the chemical and physical structure of cellulose and into its physical properties interpreted in terms of structure. It is, of course, impossible to indicate in detail all that is taking place; but very considerable progress has been made in elucidating the precise molecular arrangements in the various crystalline forms of cellulose. In this connexion the use of infra-red spectroscopy has proved particularly valuable. By means of a new technique—that is, the replacement of hydrogen in the amorphous region by deuterium—it has been found possible to separate the absorption of the crystalline regions of cellulose from that of the amorphous regions, and thus to study each region separately. The method has established the fact that two of the oxygen atoms in each pyranose unit are proton donators only, and that two of them are both proton donators and acceptors. The use of polarized infra-red gives the direction of each hydrogen bond. All this information is being carefully collated with the information obtained from X-ray analysis of crystal structure, and from organic and from physico-chemical studies.

Work is proceeding on strain birefringence. The basic theory has been worked out, and the technique has been applied to a study of the stress-relaxation of polymers at constant length. Three typical modes of photo-elastic behaviour are possible: in polymers of amorphous network the birefringence decreases with the stress; in crystalline polymers the birefringence remains constant during the relaxation; and in polymers in which stretching induces crystallization the birefringence increases as the stress decreases. In other words, the method can be, and is being, used for obtaining information regarding the physical structure and the deformation mechanism of polymers.

Two organic groups are concentrating their attention on the breakdown of cellulose during the alkali refining of tyre cord pulp, since very heavy losses take place at this stage. It is possible that the losses could be avoided if we understood better the precise mechanism of the process.

Two groups of physical chemists are studying the kinetics of the photochemical breakdown of cellulose. They have already elucidated the essential mechanism of the process; that is, that the dyestuff, under the action of light, assumes the activated triplet state and in this state it removes a hydrogen atom from the cellulose molecule. A free radical is thereby produced, which promptly combines with molecular oxygen to yield a peroxide radical which initiates the breakdown.

This work involves a study of the transient states of dye molecules, for which Prof. G. Porter's flash-photolysis technique is peculiarly suitable. A qualitative survey of the field is now complete, the spectra of all the transient states of duroquinone have been identified, and quantitative work has been commenced. It is being extended to reactions in the solid state.

The Association's technological work includes a large programme of work on blended yarns. Viscose is being mixed with acetate, cotton, nylon, 'Terylene' and 'Orlon' in turn, spun into yarn and woven into cloths of shirting and gaberdine construction. The cloths are being dyed and finished in several ways and then tested. So far as the work has gone, it is clear that in the spinning, warping and weaving there are no outstanding difficulties in producing cloths from blends. Some problems have been encountered in dyeing and finishing; but it is not expected that they will be insuperable.

Visitors showed considerable interest in the Stains direct spinner, which produces spun yarns from continuous-filament tow. The work so far has been concerned mainly with the production of viscose yarns, for which tows are fairly readily available in Britain.

An intense effort is being devoted to the short processing of rayon. The basis for the method lies in a new 3-over-4 draw frame developed by the Association. This produces a much more regular sliver than normal, with the result that at least one set of speed frames can be eliminated and single packages can be used on the ring frame, with a saving of more than 2*d*. per lb. in yarn spinning costs. Improved instrumentation is playing a vital part in this work, since it enables the mill manager to detect at once whether any of his frames are likely to give trouble.

Other machinery developments are in hand, including an important chemical engineering project recently launched. The Association is attempting to apply fluid bed techniques to yarn and fabric drying, dyeing and finishing. At first pilot plant and then full-scale plant are being erected for each application, with the view of collecting the information on which the design of commercial plant can be based. An association of British machinery manufacturers has been formed to put the invention on the market. The method offers great potential savings. For example, it is possible to dye hydrophobic fibres such as 'Terylene' and nylon by a continuous process in ten seconds instead of taking several hours in pressure vessels in batch processes. Resin baking can be carried out in twenty seconds instead of three to four minutes. Spun nylon can be singed in a tenth of a second.

Various instruments designed originally by the Association for research purposes are now being manufactured and sold by instrument firms. The two instruments which have proved most popular are the yarn speed indicator and the loom setting indicator.

The Association runs a very active member service section, which provides literature and patent surveys, examines and reports on defective fabrics, and gives immediate assistance on factory production difficulties.

The staff numbers 260, made up as follows: research staff, 86; laboratory and technological assistants, 82; engineering, drawing office, and maintenance staff, 55; and library and administrative staff, 37. The Association has just agreed to the new terms of grant for the next five-year period, under which the industry is to subscribe £270,000 a year, against a grant from the Department of Scientific and Industrial Research of £90,000 a year, although the expenditure, which for the current year is to be £322,000, will not build up to £360,000 until the end of the five-year period.

POLYMERS, BIOCOLLOIDS AND POLYELECTROLYTES

SYMPOSIUM IN ISRAEL

UNDER the title of "Polymers, Biocolloids and Polyelectrolytes in Solution" an International Symposium on Macromolecular Chemistry was held in Israel during April 3–9 under the auspices of the Commission on Macromolecules of the International Union of Pure and Applied Chemistry and the Weizmann Institute of Science, Rehovot. This was the first time that such a symposium had been held outside America or Western Europe, and the efficiency of the arrangements and success of the meeting completely justified the choice. More than a hundred foreign scientists attended, including delegates from the U.S.S.R. and Eastern European countries, in addition to an Israeli group of the same size. Sessions were held in the Weizmann Institute, the new campus of the Hebrew University of Jerusalem, and the Institute of Technology at Haifa. It is typical of the rate of development in Israel that meetings in all three centres were held in auditoria that had been completed only recently.

In addition to eighty papers, lectures summarizing recent developments in polymerization were given. The topics discussed were the Ziegler-type polymerization of olefines (Mark, of New York), organic reactions of vinyl polymers (Smets, of Louvain) and the effect of high-energy radiation on vinyl monomers and polymers (Magat, of Paris). More specialized lectures were also given at the start of every session. Space permits no more than a mention of most of the papers that were presented, and for the same reason it is impossible in some cases to give all the authors' names.

The first section of the symposium dealt with the general behaviour of polymers in solution, and included lectures on the statistical thermodynamics of polymers (Prigogine, of Brussels), hydrodynamic properties of polymer solutions (Hermans, of Leyden) and a hydrodynamic study of sedimentation and diffusion (de Groot, of Leyden). Calculations have been made of the molecular extensions of polysaccharides and polybutadienes (Eliezer and Hayman, of Jerusalem), and the matrix method employed in the theory of ferromagnetism has been shown to be useful in statistical problems involving polymers (Hill, of Bethesda). Departures from random mixing in polymer-liquid systems were considered by Gee (Manchester), and Rinfret (Montreal) summarized his recent accurate measurements of heats of mixing and partial specific volumes of polymer solutions, both of which show discontinuities that are dependent on molecular weight. Studies of the viscosity (Rempp, of Strasbourg) and vapour pressure and heat of dilution (Banderet, of Mulhouse) of solutions of paraffins and simple derivatives have been made. Interaction between solvents and cellulose derivatives (Moore, of Bradford) or nylon 66 (Valentine, of Leeds) has been measured by various techniques. Staverman (Delft) described an osmometer the 'membrane' of which is a vapour slit between two disks of sintered glass, and experiments in which diffusion through a conventional membrane was measured. The velocity of dissolution of polystyrene has been shown to depend on the molecular weight and can, after standardization, be used for measuring molecular weights (Ueberreiter, of Berlin). Studies on viscosity included the effect of shear (Eisenberg, of Rehovot) or capillary size (Lifson, of Rehovot) and the anti-thixotropy shown by solutions of poly*iso*butylene in tetralin (Crane and Schiffer, of Haifa).

Optical and electro-optical investigations were described in several papers by Cerf, Leray and Wippler (Strasbourg), Janeschitz-Kriegl (Delft), Peterlin (Ljubljana), Tsvetkov (Leningrad) and in a lecture by Sadron (Strasbourg). The present increased interest in the dielectric properties of solutions of polymers was reflected by papers by van Beek and Hermans (Leyden), de Brouckère (Brussels), Marchal and Benoit (Strasbourg) and Mandel (Brussels). For high degrees of polymerization, the root-mean-square dipole moment is found to be proportional to the square root of the degree of polymerization.

Several papers dealt with the solution behaviour of highly polar polymers. Morawetz (New York) stressed the importance of local concentrations in the molecular coil in determining the formation of association complexes. Viscosimetric and turbidimetric studies suggest that polymethacrylic acid is strongly intra-molecularly bonded, and that this may be responsible for its negative thixotropy (Eliassaf, Silberberg and A. Katchalsky, of Rehovot). The solution behaviour of chemically synthesized, branched polyglucoses (Mora, of Oxford) and the coacervation of polyamides (Turska, of Lodz) were also discussed.

As might be expected from the strong interest of Israeli scientists in this field, the behaviour of biocolloids and polyelectrolytes in aqueous solution was thoroughly discussed. Fuoss (New Haven) initiated the session with a lecture, and papers on theoretical aspects were presented by Oosawa (Nagoya), Lifson (Rehovot) and Michaeli and Overbeek (Utrecht). Topics discussed included the effect of the size of gegen-ions (Gregor, of New York) and the distance between ionizing groups (Dobry-Duclaux, of Paris). The experimental determination of the charge on the polymethacrylate ion was discussed by Jordan (Adelaide), and a new simple theory of polyelectrolytes which leads to good agreement between experiments on velocity of migration, conductivity and activity was presented by Dobry-Duclaux. Other polyelectrolytes that were discussed were polyvinylamine hydrobromide and polyvinylpiperidine (A. Katchalsky), vinyl amphoteric polyelectrolytes (Alfrey and Pinner, of New York), lithium polyphosphate (Saini, of Turin), polymethacrylic acid (Kryszewski, of Torun, Poland), sodium alginate (Allgen, of Stockholm) and the sulphate of aminoacetalized polyvinyl alcohol (Matsumoto, of Okayama). The electroviscous effect shown by rigid polyelectrolytes (Donnet, of Mulhouse), the interaction of ionized polyelectrolytes with polarized mercury-water interfaces (Miller, of Rehovot) and the potentiometry of polyelectrolyte gels (Michaeli and A. Katchalsky, of Rehovot) were also discussed. The unequal permeability to different ions of hydrophilic membranes impregnated with polyelectrolytes, particularly the copper ferrocyanide and sulphuric acid/'Cellophane'/barium hydroxide membranes, was studied by Hirsch-Ayalon (Utrecht).

In the field of protein and polypeptide chemistry, two papers on the surface chemistry of synthetic polypeptides (Isemura, of Osaka) and gliadin and zein (Jaffe, of Brussels) were presented. The deuterium exchange of poly-DL-alanine with water suggests that it exists in aqueous solution in a folded, possibly helical form (Berger and Linderstrøm-Lang, of Copenhagen), while a reversible transformation between helix and random coil has been found for solutions of poly-L-glutamic acid (Doty, of Harvard; Blout, of Boston). A general review of the solution behaviour of poly-α-amino-acids was given by E. Katchalsky (Rehovot); and the reversible heat coagulation of some of these was described by Noguchi (Kanazawa). Polybases (for example, polylysine) agglutinate red blood cells, altering their surface potentials (Nevo, de Vries and A. Katchalsky, of Israel), Meyer (New York) reviewed recent developments in our knowledge of the structure of connective tissue, and other proteins investigated were bovine serum albumin (Champagne, of Strasbourg) and actomyosin (Wassermann, of London).

Nucleic acids were also discussed in several papers and in two lectures by Jordan (Adelaide) and Watson (Cambridge, Mass.). These polymers have been investigated by a variety of physico-chemical techniques: for example, the ultra-centrifuge (Shooter and Butler, of London; Desreux, of Liège), light-scattering (Pouyet and Weill, of Strasbourg), streaming birefringence (Wahl, of Paris; Mathieson, of Nottingham), electrophoresis (Mathieson) and titration (Peacocke, of Birmingham; Mathieson).

Carbohydrates also received some attention. In a most interesting paper, Usmanov (Tashkent) discussed the physico-chemical behaviour of native cellulose and showed that the molecular weight increases steadily as the cotton fibre becomes older, so that the biosynthesis of cotton is apparently a polycondensation process. Spectroscopic studies of the ageing of starch were described by Samec (Ljubljana), while other carbohydrates investigated were levan, a polymer of D-fructose (Feingold and Gehatia, of Israel) and the cycloglucans (Freudenberg, of Heidelberg). Although cupriethylene diamine and cuprammonium hydroxide can be used as solvents in the molecular fractionation of cellulose, they are not recommended because of the degradation that may occur (Sihtola, of Helsinki). Theoretical aspects of polydispersity were considered by Hultin (Stockholm) and Daune (Strasbourg). The swelling of regenerated cellulose (Nowakowski, of Lodz), the sorption and diffusion of organic vapours by ethyl cellulose (Barrer and Barrie, of London) and adsorption on glass-like polymers (Kargin, of Moscow) were also investigated. The flexibility in solution of molecules of hyaluronic acid was reported by Rowen (Los Angeles).

Miscellaneous studies on vinyl polymers included the effect of branching on the solution properties of polyethylene (Trementozzi, of Springfield, Mass.; Mussa, of Turin), the irradiation of polymers in solution (Charlesby and Alexander, of England), the swelling of graft copolymers of acrylonitrile on polyethylene (Chapiro, of Paris) and the preparation of various graft copolymers (Mesrobian, of Brooklyn). Finally, the preparation and properties of several nitrogen-containing polymers were described: for example, polyaminocarboxylic acids and polyvinylamides (Smets, of Louvain) and poly-N-vinylpyrrolidone (Breitenbach, of Vienna).

It is to be hoped that this highly compressed survey gives some idea of the tremendous variety of topics discussed. This catholicity was deliberate, as one of the objects of the organizers was to bring together workers on biocolloids and synthetic polymers so that cross-fertilization of ideas could take place. Judging by the animated discussions that took place inside and, to an even greater extent, outside the lecture halls, this aim was fulfilled. All the papers, together with the discussions, will be printed in full in a special issue of the *Journal of Polymer Science*.

L. VALENTINE

PROGRESS IN THE STUDY OF THE BRITISH FLORA

KNOWLEDGE of the British flora has advanced during the past decade at a rate which has never been equalled before. New techniques and a fresh approach to old problems have resulted in rapidly increasing progress, and the present is therefore an appropriate time for review of old and new methods with the object of suggesting the most fruitful lines for future development. This was the purpose of the conference arranged by the Botanical Society of the British Isles under the title of "Progress in the Study of the British Flora", which was held in Bedford College, London, during April 13–14.

The conference was opened by Prof. T. G. Tutin (University College, Leicester), who directed attention to the importance of learning to regard the flora of the British Isles as a small part of that of Europe. The insularity of British workers has not yet been entirely broken down, and a wider view can have important consequences for the future progress in the study of the British flora. To know their flora properly, British workers must enlarge their scope, and a start in this direction has already been made by experimental taxonomists and specialists in certain genera. Prof. Tutin suggested that the Society could play a valuable part in helping workers to take this wider view, and this proposal was enthusiastically supported by later speakers.

Most of the first day was devoted to consideration of old methods. Canon C. E. Raven discussed "The Early Development of a Knowledge of the British Flora". He pointed out that William Turner, the 'Father' of English botany, had little success in his efforts to identify English plants in the classical botany books until he travelled abroad. As soon as he came across the dried herbaria of Luca Ghini and the admirable pictures in Brunfels, his task became manageable. The discipline which this primary business of nomenclature involved was an exacting, and therefore very valuable, preparation for botanical studies: it gave to these early students a power of detailed observation and minute discrimination which has seldom been surpassed. Ray very seldom confused species that we distinguish, or, except when he relied on hearsay evidence, described plants which we cannot easily and accurately name. This primary business of naming, and its sequel in arrangement and classification, gave rise to study of the habitat and of problems of plant structure and physiology, and the seventeenth-century botanists got as far as was possible until the basic sciences emancipated themselves from magic and tradition. During the discussion which followed Canon Raven's paper, attention was directed to the value of these old records as a starting-point for new investigations. It is significant that some species, such as *Veronica spicata* in Cambridgeshire, have remained for a period of three centuries in the same localities without extending their range, while others have shown rapid spread in much shorter periods.

The next paper, by Mr. J. E. Lousley, considered "The Contribution of Exchange Clubs to Knowledge of the British Flora". When large-scale organized exchange of herbarium specimens was started in Edinburgh and London in 1836, facilities for studying dried and localized dried material were very limited indeed. For the first twenty years, their efforts were directed towards supplying herbarium specimens in large numbers to meet the need of the time. From 1857 to 1878 there was a transitional period when emphasis passed from mere exchange to the study of critical plants, which was their proper function for the remainder of their history. They provided much of the standard material now available for consultation, and the notes printed in the reports provide a record of the views of contemporary botanists on these specimens. By focusing attention on variation, they brought to notice almost all the segregates which cytology or other modern methods have shown to be of importance, and many hints for useful new work may still be found by examination of old reports and the specimens to which they refer.

Dr. J. G. Dony then followed with a paper on "The Place of the Local Flora in the Study of the British Flora". He suggested that local floras have been largely responsible for making Britain, from the botanical point of view, the best-studied part of the world and have served to collect together information on the behaviour of our plants in addition to detailed data on their distribution. There is hope that a fresh pattern for local floras will emerge from the new methods of study now available. The system of working on the basis of the squares of the National Grid which is being used for the new Cambridgeshire, Derbyshire and Warwickshire Floras shows considerable promise.

Prof. P. W. Richards described the progress of the "Biological Flora" which is appearing in parts as supplements to the *Journal of Ecology*. Since active work on this project commenced in 1940, accounts of seventy-four species have been published, and about a hundred and sixty more are in preparation; although contributors work to a schedule, the plan allows for considerable elasticity in the treatment of individual species. Several suggestions for increasing the scope of this very useful work emerged from the discussion which followed. These included a plea for more detailed cytological information, a request for really full descriptions of each species to cover characters omitted for lack of space in most descriptive floras, and a suggestion that there is a need for a central office on the lines of the Maps Scheme of the Botanical Society of the British Isles to collect autecological information and give assistance[1] and encouragement to volunteers.

On the second day of the conference all the speakers were concerned with recent developments. Mr. Keith Jones (Welsh Plant Breeding Station, Aberystwyth) directed attention to the importance of current work in cytology in his paper on "Some Aspects of Plant Variation: the Grasses". It is common knowledge that a species is not necessarily characterized by one chromosome number alone, but may embrace forms having two or more different numbers; perhaps it is not so well-realized that there can also be pronounced intraspecific variation in chromosome pairing at meiosis. This can give important information about the nature and evolutionary origin of a species. Mr. Jones showed from examples that cytological work on artificially reared seedlings can give very different results from similar work on natural populations of the same species. The experimental taxonomist is concerned with the species as it exists after natural selection has operated, and for this purpose it is necessary to collect plants in the field. Studies based on a few individuals are of limited value, and in all cases it is important that the source of material used for chromosome determinations should always be clearly stated in publications.

"The Importance of Experimental Ecology in the Study of the British Flora" was the subject of a contribution from Dr. F. H. Whitehead (Department of Botany, University of Oxford). He pointed out that descriptive ecology discloses problems and suggests hypotheses which should then be tested by experimental work at various levels of refinement. One of his examples covered recent work at Oxford on two calcifuges, *Galium saxatile* and *Holcus mollis*, and two calcicoles, *Scabiosa columbaria* and *Asperula cynanchica*. When *Scabiosa columbaria* was grown in standard water cultures, one with a high pH and the other with a low pH, there was no significant difference in the growth of the plants, and yet when grown from seed in contrasting soils the plants behaved quite differently. These differences were maintained in water cultures prepared from soil adjusted to high and low values of pH. It was concluded that the soil substance affecting growth was water-soluble, and likely to be aluminium. In water cultures with aluminium salts added, *Scabiosa columbaria* behaved in the same way as in cultures prepared from acid soils and produced a small and malformed root system. Thus, on acid soils containing aluminium this plant would be eliminated at the seedling stage during a period of drought. Although it grows especially on soils with a high pH due to a high proportion of calcium carbonate, it will grow equally well on soils rich in other bases—the effect of calcium carbonate is only secondary in making the aluminium not available to the plant. Very similar results were obtained for *Asperula cynanchica*. Examples of this kind show that problems are much more complex than has been hitherto believed, and Dr. Whitehead concluded with a plea for more experimental work of an autecological nature.

Dr. F. Rose (Bedford College, London) opened his paper with a similar plea. In considering "The Importance of Relict and Disjunct Distributions in the Interpretation of the History of the Present British Flora", he put forward hypotheses explaining modern distributions in terms of post-glacial historical changes with the view of stimulating detailed autecological work on the groups of species he mentioned. Dr. S. M. Walters (Botany School, University of Cambridge) gave a survey of the history of mapping plant distributions. In Britain, H. C. Watson in 1836 published a clear statement of the different possible methods to be adopted—area outline, vice-county, and dot maps as they later developed—but, apart from Miller Christy's map of the oxlip in 1884, his ideas were not followed up. The first published vice-county maps for the whole of the British Isles appear to be those in Sir Edward Salisbury's "East Anglian Flora" (1932), although county maps had been included in the "Cambridge British Flora" (1914–20). In visual presentation of distribution data, we have made a much later start than other European countries. Dr. Walters suggested that we could repay our debt to European phytogeography by proposing a practical, standardized method to map the European flora, and he exhibited the outline of such a method.

In the last paper delivered to the conference, Prof. D. H. Valentine (University of Durham) considered "The Study of our Flora as Part of a Whole". Using the family Primulaceae as his main example, he demonstrated the importance of looking at the British flora as a constituent part of the boreal flora as a whole, and emphasized the importance of combining cytogenetical and taxonomic investigations. He urged co-operation with botanists in Europe and the production of a European Flora as outstanding needs.

In addition to the main papers, six exhibitors read short accounts of their exhibits. Mr. A. D. Bradshaw (Department of Agricultural Botany, University College of North Wales, Bangor) described an investigation of the *Agrostis* population of a very old pasture, Port Meadow, Oxford. The composition of a sample of sixty plants on a morphological basis, confirmed by pollen fertilities, was shown to be *A. tenuis* 1½ per cent, *A. stolonifera* 3½ per cent, plants of F_1 type 70 per cent, and plants not easily ascribable to these categories, presumably F_2's or back-crosses, 25 per cent. The population is therefore composed almost entirely of sterile hybrid plants able to compete successfully with their parents under heavily grazed conditions. Miss M. E. Bradshaw (University of Durham) reviewed the distribution of the segregates of *Alchemilla vulgaris* aggr. in Britain, Mr. P. A. Gay (University College of Wales, Aberystwyth) discussed the taxonomic status of *Erica mackaiana*, and Mr. K. M. Goodway (University College of North Staffordshire) the morphological and cytological types of *Galium pumilum*. Mr. D. M. Moore (University of Durham) considered the status of *Viola lactea*, and Dr. W. S. Lacey (University College of North Wales, Bangor) described the spread of *Galinsoga parviflora* and *G. ciliata* in Britain.

Looking back over the two days of the conference, it is clear that there was general agreement that the most promising lines for furthering our knowledge of the British flora are yet closer collaboration between field and laboratory studies, and greatly increased collaboration with European botanists. It was remarkable how these general proposals kept cropping up in almost every paper and throughout the discussions, and there was enthusiastic support for some of the measures suggested for putting them into practice. The proceedings of the conference will be published by the Botanical Society of the British Isles later this year in a book under the same title.

J. E. Lousley

THE POSITIVE CONTRIBUTION BY IMMIGRANTS

A SYMPOSIUM, "The Positive Contribution by Immigrants", prepared for the United Nations Educational, Scientific and Cultural Organization by the International Sociological Association and the International Economic Association (pp. 203. Paris: Unesco; London: H.M.S.O., 1955; 600 francs, 12*s*. 6*d*. or 2.25 dollars), includes five national studies covering the United States, Great Britain, Australia, Brazil and the Argentine Republic. There is also a short survey of the economic aspect, by Brinley Thomas, which details some of the outstanding inventions or industries in the United States attributed to immigrants and suggests that the qualitative contribution of immigrants as a source of outstanding talent and of general man-power is likely to remain a vital factor in economic development. Australian economic life has been much enriched by men of diverse nationalities endowed with varied skills and aptitudes, and in reviewing recent British experience he remarks of science that in no department of human activity is it truer to say that protective barriers are a cause of impoverishment and that their removal will always redound to the benefit of the community as a whole.

Dealing specifically with Great Britain, Mr. J. Isaac quotes some examples of the wide range of scientific activities which have been influenced by alien immigrants since 1933. Of 533 Fellows of the Royal Society, twenty-one went to Britain as refugees from the Continent of Europe, and many chairs at British universities are held by such immigrants; they have participated in such achievements as the British contribution to the development of nuclear energy, and a particularly noteworthy example is that of Prof. H. A. Krebs and Prof. E. B. Chain, who have shared the Nobel Prize for Medicine. As entrepreneurs and managers, pre-war immigrants have made notable contributions, introducing new ideas or specializing in branches of trade neglected in Britain, and their contribution in the Welsh Development Area in particular has received high praise in Parliament. The contribution of immigrants to the relief of Britain's post-war man-power problems has been limited by the qualified support given by British trade unions, the low standards of medical fitness, education or intelligence used for the selection of the workers, and by difficulties in finding accommodation in Britain for other members of the worker's family. Discussing the demographic aspect, Mr. Isaac points out that it would be a fallacy to assume that Britain could absorb a constant inflow of large numbers of immigrants in the future with similar favourable results, even if suitable persons were available, unless the immigrants could show that they have a special contribution to make.

In a concluding chapter, Mr. Oscar Handlin reviews generally the contributions of immigrants, particularly with reference to the depth of their influence on the host cultures and the extent to which those contributions were determined by the social conditions the immigrants encountered or by the character of the immigrants themselves. Finally, he concludes that, in a larger perspective, immigration establishes a complex of human ties and linkages that play a significant part in extending international understanding.

UNIVERSITY COURSES IN THE U.S.S.R.

On September 1, 1955, new syllabuses came into force for first-, second- and third-year students of all university faculties in the U.S.S.R. These have been described by M. G. Uroyev, of the Central Board of Universities and Institutes of Law and of Economics.

Fourth- and fifth-year students continue to follow the old courses; but there is an important addition for students in the faculties of philology, history, physics and mathematics, biology, chemistry and geography. In their seventh term they will take a course on teaching methods and, in their eighth term, will do teaching practice in schools for six weeks; during this time they will have no lectures or other work.

For a number of subjects one of the main weaknesses of the old syllabuses was that they produced specialists of too narrow a type. One of the chief demands of the new syllabuses is that they should provide conditions suitable for the training of 'broad' specialists—people with a command of the fundamentals of the sciences but with a proper preparation for work in various branches of industry and culture.

Subjects of general scientific and technical importance are given more weight in the syllabuses; for closely related degree subjects within the faculties of biology, geology, philology and geography there will be unification of the general theoretical grounding given to all students. For the first two or three years students taking kindred subjects will follow exactly the same courses, covering the same ground and devoting the same amount of time to various courses. For example, for the six different degree courses which can be taken in geology, there are twenty-seven courses which are the same for all students. These take up to 66–68 per cent of the total time of the syllabus, leaving 32–34 per cent of their time for special subject courses.

The new syllabuses provide for broader subject divisions than the old and do not, as a rule, allow for specialization within the chosen subject. Such excessively specialized degree subjects as, for example, 'the editing of literary and political writings', 'the economics of the countries of the non-Soviet East', 'world economics', 'the history of international relations', 'Darwinism and genetics' have been discarded. Inorganic chemistry, organic chemistry and analytical chemistry, which used to be independent degree subjects, have now become subjects in which one specializes inside the framework of a general chemistry degree.

The number of hours available for faculty courses and seminars has been reduced. Universities now have the right to decide for themselves the subjects and extent of faculty courses and seminars, and to discuss and approve for themselves the advance plans produced for such courses. In this way such courses and seminars will reflect the scientific work being done in the given university.

In the case of students in the faculty of biology, the reduction in the amount of time allowed for their faculty courses and seminars has made it possible to increase the time devoted to learning a foreign language, to studying teaching methods of their subject, and to physics, chemistry and botany and higher mathematics.

The importance of the independent work done by students is recognized and reflected in the new syllabuses in the following way: the number of lectures and classes at which attendance each week is obligatory has been cut down; certain classes, in which the material dealt with can well be mastered by the student independently, have been done away with altogether; and the number of pieces of independent work required from the student in different courses has been increased.

The increase in the time given to teachers' training is of major significance; the main task now is to train teachers for the senior classes of the secondary schools. As from 1956, not less than 80 per cent of each year's graduates in the faculties of philology, history, geography and biology, and not less than 60 per cent from the faculties of chemistry and physics and mathematics, will be going to work as secondary school teachers.

The actual titles of the qualification received by graduate teachers has also been changed: the diploma given to a graduate used to read "qualified in history (or mathematics)" but will now read "qualified in history and as a teacher of history in secondary schools"*.

* *Translators' note.* The translators, who have carried out their task on behalf of the Society for Cultural Relations, write that the way in which Soviet and British university 'technical terms' have been equated in the translation is not consistent. Soviet graduates, for example, do not receive degrees, but diplomas The word 'term' has been used for translating the Russian 'semestr', though this is really a half-year; but 'faculty' has been used in the Soviet way, although their faculties correspond to our schools or departments.

OVERSEAS FOOD CORPORATION

REPORT FOR 1954–55

The annual report of the Overseas Food Corporation for the year ended March 31, 1955*, is the last report which the Corporation will publish, since the balance of funds made available for investigating the economics of mechanized and partly mechanized agriculture under tropical conditions has been transferred to the Colonial Development and Welfare Fund for the use of the newly established Tanganyika Agricultural Corporation, which will continue the investigations until September 1957 and report on them in due course. The legislation establishing the new Corporation provides also for the dissolution of the Overseas Food Corporation, and accordingly this final report is accompanied not only by the usual statement of accounts for the year but also by an interim review of the work of the whole undertaking from its inception. Some of the findings and conclusions merely confirm those of other workers in the Colonial Empire; but others are original, and the report should be of value to many concerned with the development of tropical agriculture both in East Africa and elsewhere. Moreover, it indicates the excellent work carried out not merely by the Scientific Department but also in land clearing and development. The African Tenant Farmers Scheme is developing satisfactorily in all three areas, and results have justified a continued extension of the Scheme. There is now every probability of consolidating one of the Corporation's original areas, Urambo, into an economic communal enterprise based on a flue-cured tobacco economy, and experience gained in cattle-ranching in Kongwa indicates that the potentialities of that area for beef production are good.

---

* Overseas Food Corporation. Annual Report and Statement of Accounts for the Year ended 31st March, 1955. Pp. viii+183+8 plates. (London. H.M.S.O., 1955.) 6*s*. 6*d* net.

The report thus indicates the real dividend that has accrued from the vast investment in the original Groundnut Scheme, and the chapter reviewing the scientific and experimental work over the whole period, which includes a list of published papers as well as an outline of present and future lines of research, should be of some general scientific interest. The areas in which the work has been done represent vast tracts of Africa which, if they could be opened up and economically developed, would play a major part in the development of those territories. Since the revised agricultural plan was introduced in 1951, the Corporation has had to dispense with the services of more than 1,100 Europeans and 14,700 Africans, most of whom have found satisfactory employment elsewhere, almost three out of every four Europeans remaining in Africa.

Steady progress was made in the investigations during the year, and although it is yet too early to say which size of farm and method of farming will eventually prove to be the most economical, the farm with 1,000 acres under crop appears to have a distinct advantage over those having 1,500 and 2,000 acres under cultivation in allowing a higher degree of supervision, while a combination of annual and perennial crops should prove the safest and most remunerative in the long run. As a result of experience during the past four years and with the advice of the Empire Cotton Growing Corporation and the Department of Agriculture, Tanganyika, it has been decided to discontinue cotton in Nachingwea, chiefly owing to the incidence of red bollworm.

The scientific and experimental work carried out during the past five years or more has covered soils and soil fertility, agronomy, pests and diseases, the residual effect of fertilizers, nitrate accumulation, rainfall and weed control, chiefly with reference to groundnuts, soya, maize, sorghum, sunflower and cotton. It has been shown, for example, that, for the successful production of groundnuts and the harvesting of a good final population, early planting and harvesting at the correct time are of particular importance and much more important than cultural methods. Early experiments have shown the great value of seed dressings of the organic mercurial type for improving stands, two dressings based on an organic mercurial and on tetramethylthiuram proving consistently better than the others. Seed-bed losses were due chiefly to a wide range of fungi, mainly of the Phycomycetes group, while fungi of the *Aspergillus niger* van Tiegh. and variants were responsible for post-emergent losses. A serious threat to the production of groundnuts is rosette disease; a virus disease transmitted by the aphis, *Aphis craccivora* Koch, and it has been established that in the Nachingwea district a local variety, Asirya Mwitunde, showed field resistance to this disease; it is hoped that selection will further raise the general level of resistance of the variety. Rosette infection has also been reduced considerably by treating groundnut seed with the systemic insecticide 'Schradan'.

The success of crop production at Nachingwea depends fundamentally on the maintenance of soil fertility and especially of soil structure so that the rainfall percolates into the soil where it falls, thus preventing soil wash at times of heavy rainfall and holding the water where the plant can use it, particularly in seasons of low rainfall. Permanent experiments have been laid down to test the value of continued application of artificial fertilizers and of two- and three-year Rhodes grass leys; but a solution must be sought along the lines of a resting phase that will reconstitute drainage channels in the soil and in soil-management methods such as ridging. Methods of stubble disposal may also be important in this context.

When the present work on producing uniform varieties of Katambli that are resistant to *Polysora* rust disease is complete, the prospect of producing good yields of maize and groundnuts appears to be reasonably high. To complete a basic rotation, a white sorghum with good resistance to central shoot fly, *Atherigona indica subfuscata*, is needed. The variety Dobbs shows appreciable resistance. Soya bean yields also require a great improvement or else other crops must be introduced to provide breaks between successive cereal crops since, if these form too high a proportion of a rotation, the danger of serious losses from *Striga* is high. Work to produce a suitable sorghum and on breeding and selecting higher-yielding varieties of soya has commenced, as well as on sunflower and castor bean.

A study on the economic usage of fertilizers is projected. Even on one soil yields vary from field to field, and the continued application of phosphate on some of the older fields may have improved their phosphate status. Groundnuts generally respond well and economically to 100 lb. of single superphosphate. Maize often responds well to 100 lb. of single phosphate and 100 lb. of ammonium sulphate under experimental conditions; but the economic value of the fertilizer under production conditions is doubtful, while the response of soya and sorghum to fertilizers is low and unlikely to be economic. Future work should accordingly be directed to assess the value of the fertilizer for rotations rather than for individual crops.

Soil types on the catena vary greatly, and full utilization of these would assist the maximum utilization of land; but to use the easily erodible types is a work of great magnitude. So far, erodible types that have been cleared have been laid down as cashew plantations, but their use as pasture in a system of cattle management designed to bring fertility uphill is worth considering. Research at Kongwa is now devoted to pasture studies, particularly of the effects on natural pasture of grazing at different seasons of the year and intensity of grazing. Other investigations include the improvement of pasture by planting various mixtures and numbers of plants, seed-rates with and without superphosphate, seed production, protection of sown seed against ants, and the selection of improved strains of a wide variety of grasses. A study of 'dry farming' demonstrated that benefits of dry farming can be achieved with a protective covering of a short-season shallow-rooted grass, and that weeds and self-established grasses extract as much water as do heavy crops of maize and sorghum.

Urambo is a typical area of miombo bush, and the clearing is surrounded with forest heavily infected with *Glossina morsitans*. Recommendations made by the East Africa Tsetse and Trypanosomiasis Research Organization for controlling sleeping sickness and the fly population have been adopted by the Corporation and modified as experience indicated; but an experiment in the elimination of fly population by air spraying indicated that the cost—£1,000 per square mile—is not warranted unless immigration f further flies is impossible. Discriminative clearing as proved very successful around Tabora, and a lan has been adopted to eliminate breeding areas nside the barrier clearing, to strengthen the barrier learing so that the bush inside is isolated, and to educe the pressure on the outside of the barrier by iscriminative clearing for two miles into the bush ll around the area. The results should be apparent uring the next two years. It is not anticipated that immigration will ever be completely prevented; but the danger can be substantially eliminated by the destruction of all habitat inside the barrier. If cattle are to be kept economically, cover in which 'immigrants' can live should be eliminated so far as possible from the bush around the grazing area. The present acreage of tobacco and consequent use of firewood for curing should ensure automatic clearing of most of the inside bush in future.

STERIC EFFECTS IN ANIONOTROPIC REARRANGEMENTS*

By Prof. E. A. BRAUDE, Dr. J. A. COLES, Dr. E. A. EVANS
and Dr. C. J. TIMMONS

Chemistry Department, Imperial College of Science and Technology, London, S.W.7

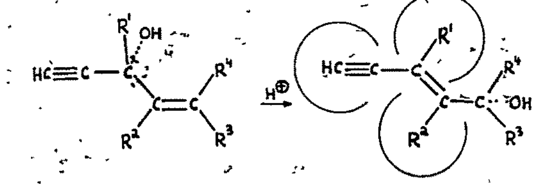
THE concept of steric hindrance, as applied to the reactions of organic compounds, has undergone a great deal of elaboration in recent years. Two main types of phenomena may be distinguished, though they are necessarily interconnected: those which arise primarily from spatial resistance by the molecule undergoing change to the approach of the reagent ('kinetic' effects); and those which are due mainly to either an increase or a decrease in steric strain in going from the reactant to the product ('thermodynamic' effects). Steric effects of thermodynamic origin have been rather less fully studied than those of kinetic origin; yet the former should be more readily amenable to quantitative interpretation since the reactivity differences will, in general, bear a more direct relationship to the physical properties of the reactants or products. We have established such a correlation between the rates of formation and the electronic spectra of certain conjugated systems, and since the principles involved should be of general applicability, a summary is presented here.

The reactions concerned are acid-catalysed anionotropic rearrangements of the type $X\text{—C(OH)—C=C} \rightarrow X\text{—C=C—C(OH)}$, where X is an acetylenic, ethylenic or phenyl group. Previous studies have shown[1] that, under the usual conditions, these rearrangements proceed via the corresponding oxonium ions as indicated below, and are normally facilitated by electron-donating substituents, such as methyl, as would be expected for a reaction involving preliminary addition of a proton. The present data cover a range of reaction-rates of more than 10^{10}, and show that the differences of rate are largely due to changes in the energies of activation.

Table 1. REARRANGEMENTS OF ALKENYLETHYNYLCARBINOLS (I) → (II)

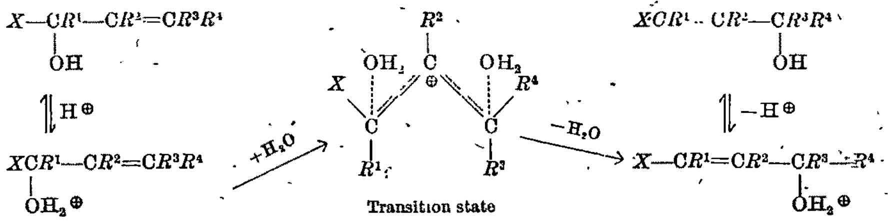
R^1	R^2	R^3	R^4	k'	ΔE_A	$\Delta\Delta E_A$	$\lambda_{max.}$	ε
H	H	H	H	0·00001	—	—	2230	13,500
Me	H	H	H	0·0002	−1·8	0·0	2235	13,500
H	Me	H	H	0·00005	−1·0	0·0	2230	13,500
H	H	Me	H	0·0006	−2·5	0·0	2235	13,500
H	H	Me	Me	0·13	−5·7	0·0	2240	13,000
Me	H	Me	H	0·09	−5·5	−1·2	2235	13,000
Me	H	Me	Me	4·0	−7·7	−0·2	2240	12,500

In this and the following tables, k' are the specific first-order rate-constants (min.$^{-1}$) in 60 per cent aqueous dioxan-hydrogen chloride at 30°, and λ_{max} and ε are the wave-lengths (in A.) and molecular extinction coefficients of maximal near ultra-violet absorption of the rearrangement products. For the meaning of other symbols, see text; ΔE and $\Delta\Delta E$ values are in k.cal./mol.



(I) (II)

When X is C≡CH, the accelerating influence of methyl substituents is apparent at each of the positions R^1, R^2, R^3 and R^4, and the effects of several substituents when expressed as the decrease in energy of activation ($-\Delta E_A$) are approximately additive (Table 1). No steric hindrance in the resulting conjugated vinylacetylene system is indicated by scale projections, even in the highly substituted derivatives, and this is borne out by the fact that the characteristic electronic spectra of the products show only minor differences in this series.



Quite a different situation is encountered when X is Ph (Table 2). Methyl substituents again cause an acceleration at R^3 or R^4; but at R^1 or R^2 they produce a decrease in rate and an increase in the energy of activation, which can be expressed as the difference ($+\Delta\Delta E_A$) between the observed and the additive or calculated values. These retarding effects are evidently not electronic and may therefore be presumed to be steric; but they can scarcely be of kinetic origin

(III) (IV)

since substituents at R^1 or R^2 will cause no appreciable hindrance either to the attachment of a proton to the hydroxyl group, or to the approach of a solvent molecule to the carbon atom bearing R^3 and R^4. The scale projections indicate, however, that methyl substituents at R^1 and R^2 will prevent the styrene system formed in the reaction from taking up a uniplanar conformation owing to interference with the *o*-hydrogen atoms of the phenyl group; they also show that interference will be less severe for a substituent at R^1 than at R^2. Now, non-planarity is well known to decrease the resonance energy associated with a conjugated system and will therefore raise the energy-level of the products with respect to the reactants, that is, reduce the resonance energy gain ($+\Delta E_R$) accompanying the rearrangement. Further, since conjugation already becomes partially effective in the intermediate stages of the act of isomerization, non-planarity will also raise the energy-level of the transition state, that is, increase the energy of activation. Thus, the retarding influence of methyl substituents at R^1 and R^2 clearly represents an example of 'thermodynamic' steric effects.

The non-planarity of the hindere styrene derivatives is reflected i their electronic spectra. In eac case where the formation of th conjugated system is stericall retarded, the rearrangement pro duct exhibits a maximum at th usual wave-length, but of reduce intensity (Table 2); and th greater the retardation, the large the drop in the absorption coeffi cient (ε). It has recently bee shown[3] that such spectral effect permit the calculation of the mea interplanar angle θ in the ground state by the simple relation $\varepsilon/\varepsilon^0 = \cos^2\theta$, where ε^0 is the absorptio coefficient for the unhindered paren system. If we make the assump tion that the dependence of resonance energy on interplanar angle obeys a simila relation $E_R/E_R{}^0 = \cos^2\theta$ ($\cos^1$ to $\cos^6$ function have been advocated; but the $\cos^2$ function i the simplest which passes through the fixed point when θ is 0, 90° and 180°), we can deduce from th spectral data the *loss* in resonance energy gai ($-\Delta\Delta E_R$) due to steric hindrance. A comparison o these values with the increase in activation energ ($+\Delta\Delta E_A$) derived from the rate-measurements wil provide a direct measure of the relative importanc of resonance in the transition state and in the fina product. The ratios ($+\Delta\Delta E_A/-\Delta\Delta E_R$) found ar approximately constant and not far from unity indicating that resonance stabilization is about equa in the transition states and in the products. Thi conclusion is in accord with the mechanism show above, the transition state of which is essentially strongly solvated carbonium ion. The extra resonanc energy of such an entity would be expected to b intermediate between that of the corresponding semi conjugated neutral system (about $\frac{1}{2}\Delta E_R$) and tha of the corresponding free charge-resonance system[3], (about $2\Delta E_R$), that is, close to that of the neutra conjugated system (ΔE_R). The actual values o $\Delta\Delta E_A/\Delta\Delta E_R$ depend, of course, on ΔE_R, estimate of which vary considerably. We have chosen 7 k.cal for the styrene system and 5 k.cal. for the butadien system as reasonable figures.

(V) (VI)

Similar results have been obtained in the formatio of the butadiene system by rearrangement of di ethylenic alcohols[5] (Table 3). Once again, methy substituents in the 'outer' positions R^3, R^4, R^6 an R^7 accelerate the isomerization, while those in th 'inner' positions R^1, R^2 and R^5 retard it. As before retardation goes together with non-planarity of th conjugated system formed, as indicated by scal projections and by the decrease in intensity of the characteristic bands in the electronic spectra. With methyl substituents at either R^1 or R^2, but not simultaneously at R^7 or R^5, the steric retardations are relatively small ($+\Delta\Delta E_A < 2$ k.cal./mol.), since only methyl-hydrogen interference will occur. On the other hand, with methyl substituents at R^1 or R^2 and simultaneously at R^7 or R^5, as in the last two examples in Table 3, the steric retardations are large ($+\Delta\Delta E_A > 4$ k.cal./mol.), since in these cases interference between two methyl groups is involved. The $(+\Delta\Delta E_A/-\Delta\Delta E_R)$ ratios, though of the same order, are more variable in this series and the differences can be interpreted; but their limited accuracy does not in our opinion justify carrying the analysis further at present. The estimated or observed values of $(+\Delta\Delta E_A/-\Delta\Delta E_R)$ could obviously be used, however, to calculate the relative rates of formation of other hindered conjugated systems from their electronic spectra, or *vice versa*.

SPIRACULAR CONTROL OF DISCONTINUOUS RESPIRATION IN INSECTS

By Dr. HOWARD A. SCHNEIDERMAN

Department of Zoology, Cornell University, Ithaca, New York

THE respiration of many groups of insects is remarkable in that metabolic carbon dioxide is retained within the insect and released during brief periods in 'bursts'[1]. In diapause pupæ of the Cecropia silkworm, *Platysamia cecropia*, more than nine-tenths of the metabolic carbon dioxide is stored and then released in brief bursts which occur from once every week to many times per hour, depending on the temperature and metabolic rate. The remaining carbon dioxide escapes during the interburst period. The uptake of oxygen, unlike the release of carbon dioxide, is continuous and steady. If the spiracles are sealed with paraffin, virtually all the respiratory exchange ceases; the spiracles are, therefore, the site of both the discontinuous release of carbon dioxide and the simultaneous continuous uptake of oxygen[2].

Since oxygen uptake is continuous, the spiracles must remain partially open between bursts, permitting oxygen to diffuse in. Thus we are confronted with two perplexing facts; namely, that oxygen enters the insect during the interburst period at many times the rate at which carbon dioxide leaves, and that the insect releases its carbon dioxide periodically. The latter is the simpler to explain and is considered here.

The fact that the spiracles are partly open between bursts has led some to conclude that the opening and closing of the spiracles cannot be responsible for the discontinuous release of carbon dioxide[3]. During the past two years, however, we have obtained considerable evidence that the cycle of retention and release of carbon dioxide does indeed result from the cyclical activity of the spiracles. The aperture of each spiracle is regulated by a spiracular valve served by a closer-muscle. When this muscle relaxes, the valve opens because of its own elasticity and because of the tension of an elastic ligament which opposes the closer-muscle. The muscle receives nerve fibres from the corresponding segmental ganglion and from the median nerve of the previous segment[4].

The central importance of the spiracular valves in the discontinuous release of carbon dioxide was suggested by the observation of Buck *et al.* that intubating the spiracles of *Agapema* pupæ eliminated the bursts of carbon dioxide[5]. Similarly, we observed that excision of the valve from one of the fourteen functional spiracles of a *Platysamia* pupa caused carbon dioxide output to become continuous. Lowering the metabolic rate of these surgically treated pupæ by keeping them at 10° C. did not cause the bursts to reappear. Indeed, the only manœuvre that restored the discontinuous release of carbon dioxide was the sealing of the open spiracle. It appears from this experiment that all the spiracles remain nearly closed during the interburst, preventing carbon dioxide from diffusing out in substantial quantities, and that one or more of the spiracles opens during a burst. The spiracular valves are thus the key to the discontinuous release of carbon dioxide.

The activity of the valves in the living pupal silkworm was recorded by following the leading edge of a valve with the hairline of an ocular micrometer, the movements of which were translated into a kymograph trace by a system of pulleys and levers. Fig. 1 is a portion of a typical record of the activity of an abdominal spiracle of a *Platysamia* pupa. The ordinate of the trace shows the width of valve-opening in arbitrary units, while the abscissa denotes the duration of the opening. A consistent pattern of valve movement occurred in cycles lasting 45 min. to 2 hr. After a period during which it remained closed and motionless, the valve fluttered for about 15 min., and then, within a minute, the valve movements progressively increased in amplitude until the valve opened fully. Swaying slightly, it remained open for several minutes. Then it alternately opened and closed for several minutes, and the valve movements gradually decreased in amplitude and duration until the valve closed altogether. Following this, the valve remained motionless until the fluttering preceding the next period of wide openings. This cycle was repeated over and over and apparently represented the normal behaviour of the spiracle. Manometric observations of the carbon dioxide output of this pupa revealed bursts of carbon dioxide at intervals of 30 min. to 2 hr. A similar correlation between the frequency of carbon dioxide bursts and periods when the valve was widely opened has been consistently observed in all other silkworm pupæ studied. It is evident that the periodic release of carbon dioxide by the insect results from a periodical prolonged opening of the spiracles which I term a 'burst'. Moreover, it appears that the continuous interburst inflow of oxygen and outflow of carbon dioxide is not the result of occasional small openings of valves between bursts. Rather, oxygen enters and a trace of carbon dioxide leaves through the very small opening which must persist after the valve closes.

Variations in the ambient tensions of oxygen and carbon dioxide exert a profound effect on this cycle of valve activity (Fig. 2). Increasing the oxygen tension above the 21 per cent in air progressively eliminated the interburst fluttering but left the burst-frequency unaltered. Decreasing the oxygen tension below 21 per cent progressively increased the interburst fluttering until, at tensions below 15 per cent, the bursts disappeared and the valve fluttered continuously. Finally, when the oxygen tension fell to about 5 per cent, the valve remained wide open, closing only intermittently. As carbon dioxide tension increased above 5–8 per cent, the frequency of bursts increased and the duration of the bursts lengthened. In 15 per cent carbon dioxide the valves fluttered continuously, and at still higher tensions of carbon dioxide they behaved as they did in 5 per cent oxygen.

These findings explain the previous manometric findings that increasing ambient oxygen tension decreased the interburst output of carbon dioxide, that increasing the carbon dioxide tension above 5–8 per cent increased the frequency of carbon dioxide bursts, and that low tensions of oxygen and high tensions of carbon dioxide eliminated the discontinuous respiration[2]. Moreover, the observations suggest that within the insect the normal stimulus for cyclical valve activity is a combination of decreasing internal tension of oxygen and increasing internal tension of carbon dioxide during the interburst period. The following hypothesis is consistent with all the observations.

Immediately after a burst the valves are closed; but they leak sufficiently to permit some inflow of oxygen and outflow of carbon dioxide. The valve opening, however, is so small and the gradient driving oxygen in so slight that oxygen inflow does not match oxygen utilization, and the oxygen tension within the tracheal system of the insect falls. When the intratracheal oxygen tension falls to about 10 per cent, the spiracular muscle partially relaxes and the spiracle opens, permitting oxygen to enter. This increases the oxygen tension, and the valve promptly closes. This pattern of opening and closing is repeated and represents the period of fluttering prior to a burst. During the interburst period some carbon dioxide escapes, but at a rate less than that of its production. The internal carbon dioxide tension ultimately reaches a critical threshold and the closer-muscle relaxes, the valve opens widely in a burst, carbon dioxide pours out and oxygen flows in. As the internal carbon dioxide tension now decreases and the internal oxygen tension increases, the valve begins to close and open periodically with diminishing width and duration of opening until finally it remains closed and the cycle is completed.

Further support for this hypothesis comes from the following observations on animals with intubated spiracles. A series of pupæ had tiny glass tubes inserted in several of their spiracles beyond the spiracular valves, placing their tracheal system in free communion with the air. The carbon dioxide tension within the insect fell and the oxygen tension rose as the gas tensions within the insect approached that of the outside. In such pupæ, the unintubated spiracular valves remained tightly closed for many days, presumably because the normal stimuli triggering spiracular activity were absent. The spiracles opened, however, when the ambient oxygen tension was reduced below about 10 per cent or the carbon dioxide tension raised above about 10 per cent. Further, we noted that the threshold concentration of carbon dioxide needed to trigger the opening of the spiracles diminished as the oxygen tension was decreased below 21 per cent[6].

Having established a possible sequence of events to account for the cyclical activity of the spiracles, we come to the question of the co-ordination of this activity and the location of the chemoreceptors sensitive to changes in gas tension. Although a localized stream of carbon dioxide could cause individual spiracles to open, in the normal insect the spiracular valves were co-ordinated. When the valves opened in a burst or closed at the end of one, they did so within a minute of each other, though when they fluttered the pulsations were not in exact synchrony. Moreover, in an intubated pupa the carbon dioxide and oxygen thresholds for spiracle opening were very similar in the several spiracles of an individual. There is, however, no indispensable central respiratory centre for all the spiracles;

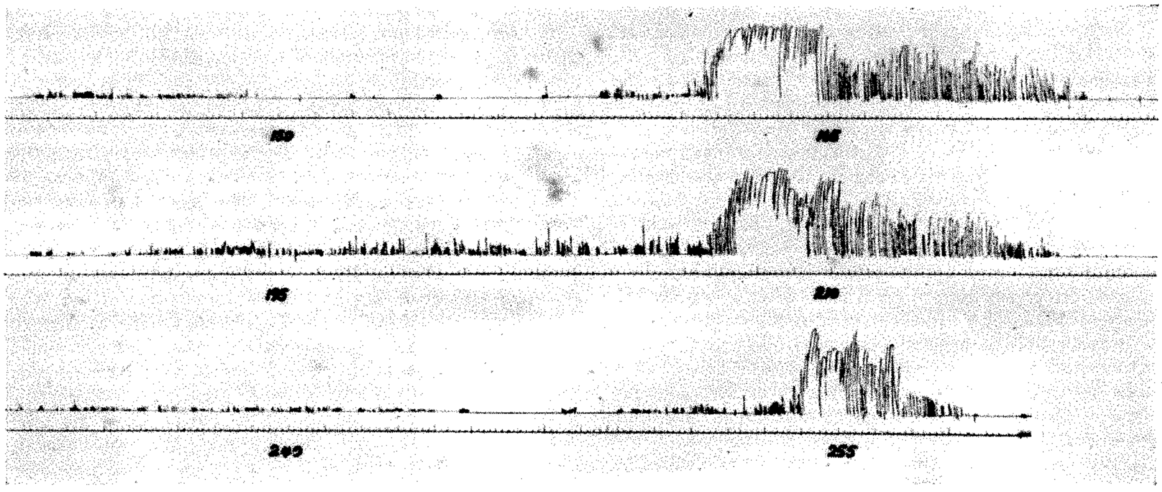

Fig. 1. Portion of a typical record of the valve movements of the third abdominal spiracle of a *Platysamia* pupa in diapause at 25° C.

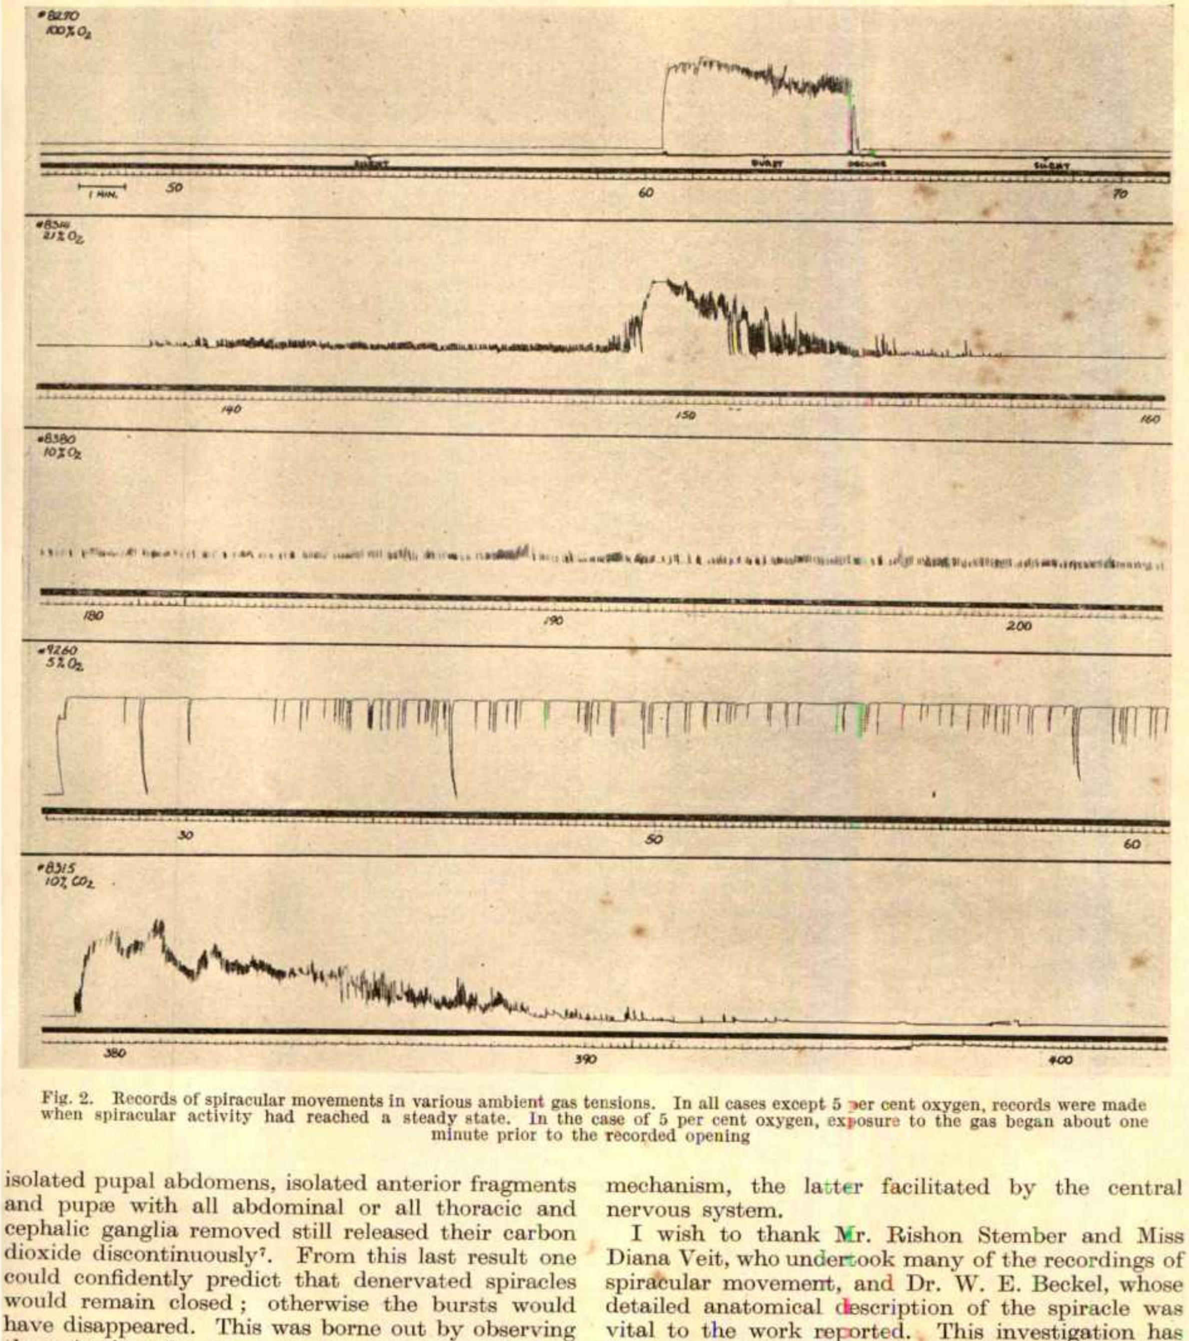

Fig. 2. Records of spiracular movements in various ambient gas tensions. In all cases except 5 per cent oxygen, records were made when spiracular activity had reached a steady state. In the case of 5 per cent oxygen, exposure to the gas began about one minute prior to the recorded opening

isolated pupal abdomens, isolated anterior fragments and pupæ with all abdominal or all thoracic and cephalic ganglia removed still released their carbon dioxide discontinuously[7]. From this last result one could confidently predict that denervated spiracles would remain closed; otherwise the bursts would have disappeared. This was borne out by observing the spiracles of pupæ with one or more segmental ganglia removed: the spiracles serving the denervated segments remained closed in air. They opened in low oxygen tension or high carbon dioxide tension but were somewhat less sensitive than innervated spiracles of the same individual[8]. The response persisted for at least forty-two days after denervation. The stimulus for contraction of the closer-muscle of the spiracle after it was deprived of all central nervous connexions remains for the present a mystery. Efforts to demonstrate a peripheral ganglion near the muscle have thus far met with failure. Further histological as well as pharmacological studies of the spiracular mechanism are under way in an effort to clarify this issue. Present evidence points to a peripheral sensory mechanism and a peripheral motor mechanism, the latter facilitated by the central nervous system.

I wish to thank Mr. Rishon Stember and Miss Diana Veit, who undertook many of the recordings of spiracular movement, and Dr. W. E. Beckel, whose detailed anatomical description of the spiracle was vital to the work reported. This investigation has been supported by Grant *H*-1887 from the National Heart Institute of the U.S. Public Health Service and the Sage and Sackett Funds of the Zoology Department of Cornell University.

The Flying-Spot Monochromatic Ultra-Violet Television Microscope

ATTENTION has been directed by Young and Roberts[1] to the advantages of utilizing the flying-spot technique for the production of absorption images of living cells at 2600 A. These advantages are the immediate visual presentation of the image and a great reduction in the amount of ultra-violet radiation necessary for the production of the image, the latter advantage being due to the much greater quantum efficiency of photocathodes over photographic emulsions.

Practical realization of these advantages has now been made possible because of the utilization of new deep ultra-violet scanning cathode-ray tubes and ultra-violet photomultipliers of high quantum efficiency, in conjunction with certain recent developments in technique we have devised. These developments consist of the employment of 4-sec. frame-sweep speeds, 60-cycle line presentation on a radar (cathode-ray) tube, and photographic integration of the image on the monitor tube. The purpose of the 4-sec. frame, 60-cycle line is to reduce the amount of radiation received by the specimen while at the same time obtaining the maximum signal-to-noise ratio on the presentation tube ; photographic integration then allows for a further increase in the signal-to-noise ratio and is obtained by exposing the photographic plate to several successive frames. The image then builds up in proportion to the number of frames, while the statistically random distribution of the noise allows it to build up as the square root of the number of frames. The limits of this integration process are : (*a*) the signal-to-noise ratio of the specimen image on the monitor tube should be sufficient to allow for ease in focusing the microscope ; (*b*) the total integration time should be short when compared to particle movement within the living cell ; in the case of mitosis this would perhaps be of the order of one minute or less. In the observation of non-living material (*b*) does not apply, and integration may be virtually infinite. Improved ultra-violet scanner tubes are in the process of construction which will provide a greatly improved signal-to-noise ratio ; the necessity of photographic integration will be minimized and may be obviated, dependent on the image-forming characteristics of the specimen.

Flying-spot ultra-violet television microscopy should show considerable advantage over television-camera ultra-violet microscopy since the television camera tube has a considerable background of noise, not due to statistical arrival of photons ; and the lack of really high gain between its photocathode and the associated amplifier means that the first valve contributes noise. Neither of these disadvantages applies to photomultiplier tubes.

The accompanying illustrations demonstrate the principle of photographic integration. The specimen is a tissue-culture preparation of the Hela strain of human cancer cells, mounted between 'Vycor' cover slips. The specimen was scanned by a monochromatic ultra-violet spot at 2600 A. with a band-width of 100 A. The photographs show identical absorption images of the same living cells, and differ only in the number of frames integrated. Fig. 1 is the result of exposure of the plate to one frame, Fig. 2 to sixteen frames, and Fig. 3 to sixty-four frames.

Thanks are due to Mrs. O. Walker for the photographs and to Mrs. D. Robbins for the tissue culture preparations ; to the E.M.I. Research Laboratories, Ltd., and the Allen B. Du Mont Corporation for the development of the flying-spot scanner tubes. Grants-in-aid were made by private citizens of Dallas, Texas, the Damon Runyon Memorial Fund, the Rockefeller Foundation, and the Texas Instruments–Geophysical Service, Inc., Foundation.

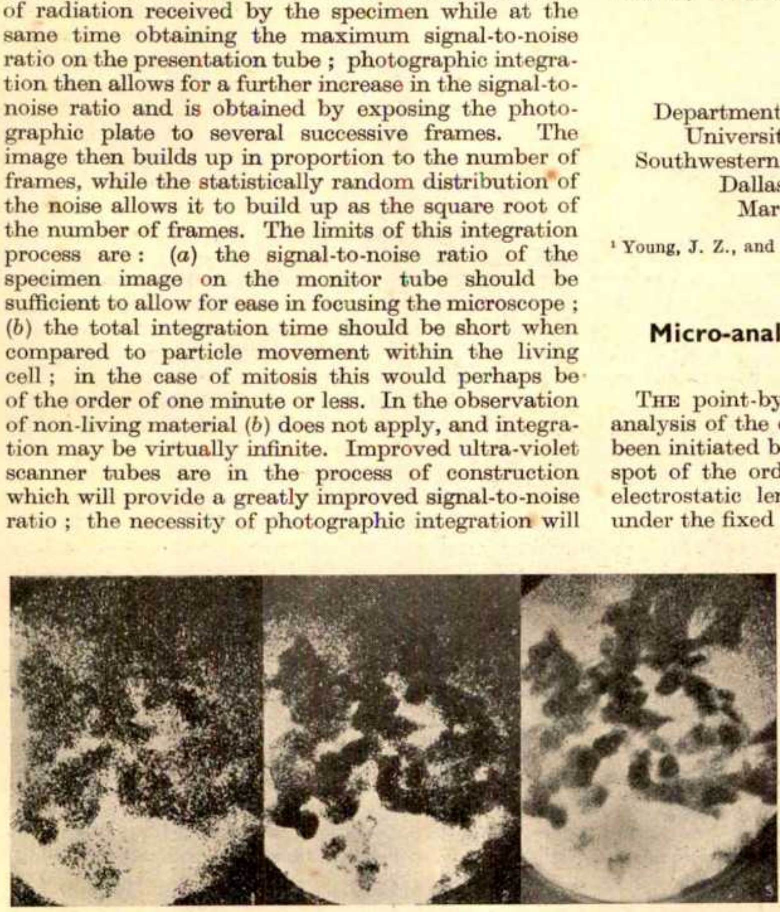
Micro-analysis by a Flying-Spot X-Ray Method

THE point-by-point investigation of a surface by analysis of the characteristic X-ray line emission has been initiated by Castaing[1]. He obtained an electron spot of the order of 1 micron in diameter with an electrostatic lens system and moved the specimen under the fixed spot ; the point examined was identified by means of an optical viewing system. Analysis is greatly facilitated if the electron spot is scanned across the specimen and if a counter is used for collecting part of the emitted X-rays. The signal from it can be transferred to a cathode-ray tube scanned in synchronism, so that a picture is displayed of the part of the surface under investigation. Such a system is similar to the electron scanning microscope[2]. It differs appreciably from that proposed by Pattee[3], in which an electron spot scans a thin target of a pure metal next to which is placed the specimen to be examined, so that image con-



(1) One 4-sec. frame. (2) Four 4-sec. frames. (3) Sixteen 4-sec. frames. Monochromatic ultra-violet absorption images of living Hela cells at 2600 A., bandwidth 100 A.

trast is due not to emission but to differential absorption, as in the normal form of X-ray projection microscope[4].

We have built and operated successfully a flying-spot X-ray microscope of the emission type. Magnetic lenses have been used, so as to obtain a smaller electron spot or alternatively a greater beam current in a spot of the same size, as compared with electrostatic lenses. By employing a proportional counter, a particular X-ray line can be selected as the imaging signal, so that in the picture only those parts of the surface appear bright which contain a given element. Fig. 1,*A*, *B*, *C*, *D* shows the degree of differentiation obtained from an impure sample of beryllium. Fig. 1,*A* is obtained when all quanta are recorded, and Fig. 1,*B*, *C*, *D* when those of certain energies only are passed by the pulse analyser. The magnification and contrast of the image can be controlled electronically and the area of specimen scanned may be varied at will. By stopping the electron probe over a selected point on the surface, the spectrum of X-rays emitted by it may be mapped by varying the band accepted by the pulse analyser. In this way the bright areas in Fig. 1,*B*, *C*, *D* were identified as manganese, nickel and calcium respectively.

In quantitative analysis the ability to discriminate one element from another is limited to approximately $\Delta Z \gg 4$; the natural width of a characteristic line is considerably broadened by the proportional counter. The accuracy can be greatly improved by using a simple crystal spectrometer for initial analysis of the X-rays. A new magnetic lens has been designed and constructed which allows this to be done through one exit port, while through a second port another portion of the X-rays emitted from the surface is accepted by a scintillation counter for the purpose of image formation. Direct quantitative results for the concentration of an element can thus be obtained; it will be possible to separate neighbouring elements in the periodic table. The concentration sensitivity and accuracy of location are now the subject of detailed investigation.

Cosmic-Ray Increase observed at High Southern Latitudes on February 23, 1956

THE large, sudden increase in cosmic-ray intensity between the hours 0300 and 0400 G.M.T. on February 23 was observed at Hobart, Tasmania, Australia, and also at the Australian National Antarctic Research Expedition's bases at Macquarie Island and Mawson, Antarctica. At the same time radio fade-outs, ionospheric and magnetic disturbances were recorded. The cosmic-ray increase resembles those observed in other places on four previous occasions in association with solar flare activity, namely, on February 28 and March 7, 1942, July 25, 1946, and November 19, 1949[1].

The increase was observed at the three stations with counter telescopes, and also with a 23-litre shielded ionization chamber at Hobart. The telescopes at Hobart and Mawson have 1-metre square counter trays, the extreme tray separation being 1·5 m. At each of these stations there are two telescopes, one of which is operated vertically, the other inclined at 45° to the zenith. Each telescope contains 10 cm. of lead absorber. At Macquarie Island there is a small vertical array of four 20 cm. × 20 cm. counter trays equally spaced by 15 cm. with 10 cm. of lead between trays 2 and 3, and also between trays 3 and 4, numbering from the top tray. The trays were connected to two three-fold coincidence circuits in such a way that the intensity of particles able to pass through 10 cm. or alternatively 20 cm. of lead is recorded separately.

The time of commencement of the cosmic-ray increase observed with the ionization chamber was 0341 G.M.T., the maximum possible error of timing being estimated at ± 2 min. The rate of increase of ionization was very high, and the commencement time given above

Table 1

Station	Lower limits of percentage increase above the mean for 6 hr.			
	Ion chamber 10 cm. lead	Vertical tel. 10 cm. lead	Inclined tel. 10 cm. lead	Differential tel. 10 cm. but not 20 cm. lead
Hobart (Geomag. co-ord. 52° S., 224° E.)	135	169	67 (East)	
Macquarie Island (61° S., 243° E.)		139		360
Mawson (73° S., 103° E.)		175	185 (West)	

Cosmic ray increase commenced at Hobart at 0341 G.M.T. ± 2 min. Duration about 4 hr.

Radio fade-out observed at Sydney, 0332–0444 G.M.T.
Solar radio noise on 85 Mc./sec. observed at Sydney, 0335 G.M.T. End not observed.
Solar radio noise on 19 Mc./sec. observed at Sydney, 0335 G.M.T. Ended at 0406 G.M.T.
} Information supplied by the Radiophysics Division, Commonwealth Scientific and Industrial Research Organization, Sydney.

Radio fade-out began at Mawson, 0342 G.M.T.

Magnetic disturbance at Macquarie Island began 0333 G.M.T. Duration about 2 hr.

is the instant at which the intensity departed from the normal level by an amount equal to the 95 per cent confidence limit. The peak intensity was not observed, as the recorder went off-scale.

Recording intervals of 1 hr. were in use with the telescopes at the time of the increase, so that the peak intensities were not observed. However, by assuming that the time of commencement of the increase was the same at each recorder, it is possible to calculate the lower limits for the peak intensities. These and other relevant details are set out in Table 1.

The following comments may be made concerning the observations:

(1) The cosmic-ray increase began within a very few minutes of the accompanying radio fade-outs and the arrival of ultra high-frequency solar radio bursts at the Earth. Also, the duration of the increase was of the same order as that of the fade-outs and bursts. This suggests that on this occasion the acceleration of the particles took place on the Sun at practically the same time as the enhanced ultra-violet and radio emission. If this is so, consideration of the time of flight of the particles leads to the conclusion that the path-length cannot have been more than 1½ times the Sun–Earth distance. This is consistent with a very weak general solar magnetic field.

(2) The effect was more pronounced at low particle-energy, as shown by the large percentage increase in the low-momentum band (235–340 MeV./c for μ-mesons) detected at Macquarie Island. This is also supported by the results from the inclined telescopes, bearing in mind that the most favoured direction of approach for positive particles of low energy is from the west.

(3) No cosmic-ray decrease was observed in association with the magnetic storm which occurred on February 25. In this respect the flare effect was similar to those of March 1942 and November 1949, but differed from those of February 1942 and July 1946.

(4) The increases observed at Macquarie Island and Mawson, and possibly those at Hobart, are not consistent with the impact zones predicted using a simple dipole field[2]. Assuming that a particle must have a rigidity greater than 3 BV. to produce a meson component at sea-level, and that the solar source is 25° in diameter, the background zone cannot extend beyond lat. 51° S. Particles of rigidity greater than 3 BV. may reach higher latitudes than this in localized impact zones; but none of the stations is in such a zone. The departure from simple theory is not unexpected, as increases were observed at high northern latitudes on the four previous occasions.

(5) After correction for atmospheric pressure, the intensity at each station for a few days prior to the increase was about 2 per cent less than normal, and after the increase returned to the depressed level for a period of a few days. If this decrease is to be interpreted as a screening effect produced by magnetized gas clouds[3], it might explain qualitatively the discrepancy between the observed increases and the predicted impact zones. The magnetic disturbance observed at Macquarie Island is a further indication that complicating agencies were present at the time.

Effect of Shape on the Static and Dynamic Stress–Strain Relationship of Bonded Rubber in Compression

The stress–strain relationship of rubber under unidirectional compression with free expansions in the other two directions has been derived from the kinetic theory of rubber-like elasticity by Treloar[1] and others. These conditions can be simulated by compressing the rubber between parallel plates at which friction is eliminated by lubrication. The static compressive stress σ_s (lb./in.^{2}) is given by

$$\sigma_s = G_s(\lambda - \lambda^{-2}) \qquad (1)$$

where G_s is the static shear modulus and λ the ratio of compressed to initial height. This relationship holds true provided the lubrication is adequate. Where free lateral expansion is prevented by friction or bonding at the confining surfaces, the shape of the rubber influences the stress–strain relationships in a way that has hitherto defied systematic analysis. Kimmich[2] showed that most of the difficulty in correlating published results may be explained by the nature of the surface of the compressing plates and of the rubber, the manner of applying the stress, the thixotropic behaviour of some rubbers, and because the stress–strain relationship is not linear. As the industrial uses of rubber in compression (usually with the faces bonded to metal) are very numerous, a mathematical relation between stress

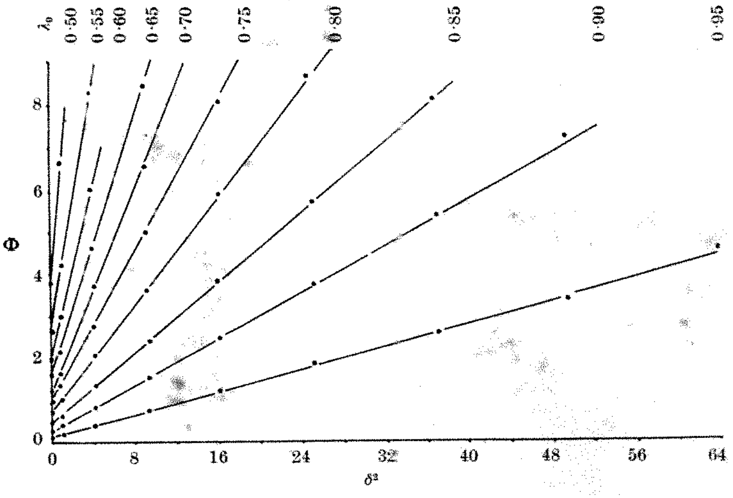

Fig. 1

and strain is essential for design purposes. It is the purpose of this communication to point out a general relationship obtained from experimental results for rubber specimens of various sizes bonded to metal plates.

From a critical discussion of the literature on shape effects, it was concluded that the static stress–strain curve of a bonded rubber can be described by

$$\sigma_s = G_s \Phi \qquad (2)$$

where $\Phi = f(\lambda, \delta)$, δ being a shape factor related to the geometry of the rubber; for example, for cylinders δ is the radius/height ratio. The above expression separates the rubber property G_s from the purely geometrical term Φ. Any change in the properties of the rubber due to its nature, to speed of test, temperature and thixotropy are therefore reflected only in the G_s term.

The stress–strain curves for bonded rubber cylinders of various values were obtained using a pure gum natural rubber vulcanizate. The values for particular λ and δ were obtained from the stress–strain curves by dividing the stress by G_s, derived from the linear relationship (equation 1) between stress and $(\lambda - \lambda^{-2})$ for the rubber compressed between lubricated plates.

Fig. 1 shows that the plots of Φ against δ^2 are linear over the ranges of shape factor and precompression studied and conform to the equation:

$$\Phi = (\lambda - \lambda^{-2})(1 + K\delta^2) \qquad (3)$$

where $K = 0{\cdot}413$. Shape factor zero ($\delta = 0$) thus corresponds to a perfectly lubricated rubber, and a bonded rubber with $\delta > 0$ differs from this ideal case by the factor $(1 + K\delta^2)$. The constant K is similar to that proposed by Hattori and Takei[3] from classical theory for small finite strains. Similar expressions to the above but differing mainly in the coefficient K and definitions of δ have been obtained for other shapes, for example, squares and rectangles.

If now a sinusoidal dynamic strain of amplitude H is superimposed upon a static compression to a height λ_0, the total stress $\sigma_T(t)$ at any time t is

$$\sigma_T(t) = \sigma_s + \sigma_D(t) \qquad (4)$$

where σ_D is the instantaneous dynamic stress, given by

$$\sigma_D(t) = G_D \int_{\lambda_0}^{\lambda_0 + H\sin\omega t} (\mathrm{d}\Phi/\mathrm{d}\lambda)\mathrm{d}\lambda \qquad (5)$$

G_D being the fundamental dynamic shear modulus at the frequency of test.

The overall dynamic stress variation σ_0 over one cycle is

$$\sigma_0 = G_D \int_{\lambda_0 - H}^{\lambda_0 + H} (\mathrm{d}\Phi/\mathrm{d}\lambda)\mathrm{d}\lambda \qquad (6)$$

As Φ increases monotonically with λ, then (from equation 3):

$$\sigma_0 = G_D(1 + K\delta^2)\,(\lambda - \lambda^{-2})_{\lambda_0 - H}^{\lambda_0 + H} \qquad (7)$$

A typical experimental graph plotting values of σ_0, for precompressions from $\lambda = 1{\cdot}0$ to $0{\cdot}55$ and superimposed dynamic oscillations $H = \pm\,0{\cdot}004$ to $\pm\,0{\cdot}086$ against $(\lambda - \lambda^{-2})_{\lambda_0 - H}^{\lambda_0 + H}$, indicates that a linear relationship the slope of which is $G_D\,(1 + 0{\cdot}413\,\delta^2)$ fits the experimental points, G_D having been obtained from a similar set of dynamic tests using lubricated faces.

The above relationships hold for the in-phase or elastic component of the complex dynamic modulus, and also for the out-of-phase or viscous components. These relationships have been applied to the published results on the static stress – strain curves of Kimmich[2], Hattori and Takei[3], and Schay and Ször[4], and for the dynamic results of De Meij and van Amerongen[5]. Without exception, the above relationships give an adequate description of the experimental results.

It is hoped to publish a fuller account of this work elsewhere, together with a further discussion using these relationships for various shapes and for various types of rubbers, including those which show marked thixotropic behaviour.

This work forms part of a research programme on the static and dynamic properties of rubber, and I thank the Council of the Research Association of British Rubber Manufacturers for permission to publish this communication.

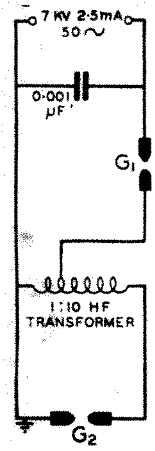
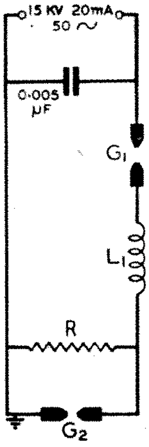
Absence of Shock Hazard with Certain Multigap Spark Circuits

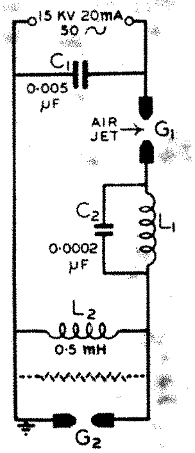
I HAVE found that the shock hazard associated with some electric spark generators is not so great as is generally believed and can be reduced to negligible proportions by appropriate design. Kaiser and Wallraff[1] and others have shown that spark-gap voltages are quite low (order of 50 V.) during discharge and that, in a twin-gap circuit similar to circuit 2, a high voltage appears across the gap G_2



Circuit 1



Circuit 2



Circuit 3

for only a fraction of a microsecond at the beginning of each discharge. Since it is known that the human body can tolerate high-voltage pulses of very short duration, a reasonable inference is that little or no shock should be felt on touching the electrodes of G_2, provided the gap continues to break down in normal fashion. Most people would be reluctant to put this to the test, and I have not seen any report of it having been done.

The experiments to be described were carried out with spark circuits of a type and power-level widely used in spectrographic analysis. In each of the circuits shown, G_1 represents the control gap determining the striking voltage, while G_2 represents the analysis gap which, for convenience in manipulation, is often unprotected by a cage.

Preliminary experiment with the safe low-energy discharge produced by circuit 1 showed that touching the electrodes of G_2 did not prevent a spark jumping the gap, at least up to 3 mm. length, and that no shock was felt. It was then practically certain that the same would hold with circuit 2, since the body currents incurred would be of the same order of magnitude and duration, though the spark currents would be much greater than with circuit 1. This was confirmed with a gap of 4 mm. at G_1, 2 mm. at G_2 and no added inductance at L_1, all electrodes being graphite. The resistance R was merely that provided by touching the electrode holders with two fingers of one hand, probably equivalent to 1,000–2,000 ohms[2]. Since the sparks produced by this circuit are highly energetic and noisy, the demonstration makes quite a spectacular display.

In later trials, however, it was found that when an inductance of 0·03 mH. was added at L_1, frequent shocks were received, even when G_2 was made very short. No improvement followed when an inductive bridge of 0·5 mH. was placed across G_2 for the purpose of by-passing any anomalous low-frequency current. After some exploration, the shocks were eventually attributed to the occurrence of misfires with some 'tailing' sparks, that is, weak sparks which follow soon after a previous spark during the period of incomplete de-ionization, when the breakdown voltage is much less than normal. Photographs showed that increasing the inductance of the discharge loop results in more frequent occurrence of tailing sparks, and de-ionization-rates appear to be so erratic that occasionally the breakdown potential of G_1 may be temporarily lower than that of G_2. Should a spark occur on such an occasion, G_2 will not fire. Blowing a 50 metre/sec. jet of air across G_1 after the manner of Enns and Wolfe[3] eliminated tailing sparks and shocks.

To ensure breakdown of G_2, a liberal excess of voltage should be provided; that is, in circuit 2, G_1 should be considerably longer than G_2. As L_1 is increased, the voltage available at G_2 is reduced (for example, when R is 1,000 ohms and L_1 is 1 mH., the calculated maximum voltage at G_2 is about 75 per cent of the initial voltage at G_1). If R be replaced by an inductance L_2, the maximum voltage at G_2 in an idealized circuit would be $L_2/(L_1+L_2)$ times the initial voltage at G_1. With both L_2 and R in parallel with G_2 the voltage would be still lower. Another consequence of increasing L_1 is that the time of rise of voltage at G_2 is lengthened, so that eventually a stage would be reached at which shocks would be possible because of the long delay in attaining the breakdown voltage at G_2. The limit in this respect was not determined. Both these dangers accompanying the increase of inductance L_1 can be overcome by placing in parallel with L_1 a small condenser C_2 as in circuit 3. For a brief period immediately after the breakdown of G_1, C_2 virtually short-circuits L_1, and thus, irrespective of the value of L_1, practically the whole of the initial voltage becomes available at G_2 with a very short time of rise. The characteristics of the succeeding discharge, for spectrochemical purposes at least, are only slightly affected by the presence of C_2, provided that C_2 is small compared with C_1.

A fuller account is to be given elsewhere of this work, and of the application of the series-gap device to removing the shock hazard from a spark-ignited arc source. In the arc circuit the isolating gap can be shorter than the exposed gap.

Fatigue of Metals under Random Loads

The stresses produced in an aircraft structure during flight are of an irregular random nature, reflecting the characteristics of the source of the stresses, namely, atmospheric turbulence. It is often necessary to try to estimate the fatigue life of a structural member under these flight loads. Usually the only fatigue data available are from laboratory tests in which the applied stress is a constant-amplitude sine wave. Miner[1] has suggested a procedure by which, knowing the fatigue life at various sine-wave amplitudes, the fatigue life under a given irregular loading may be calculated.

Many tests of Miner's rule have been made with an applied stress which is sinusoidal and the amplitude of which is varied at intervals during the test. These have shown that Miner's predicted fatigue life may differ from that measured by factors up to 30. However, to our knowledge, there had not been any fatigue tests carried out with a random stress waveform. A random-noise fatigue machine has therefore been constructed, and a typical time trace of the stress produced in the specimen is shown in Fig. 1. The fatigue machine consists of a thermionic noise

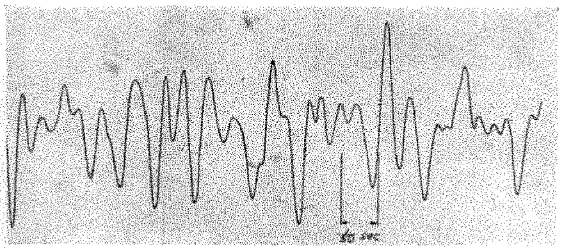

Fig. 1. Typical stress wave-form in specimen

source, the random output voltage from which is amplified by a 20-W. amplifier. This drives a moving-coil vibrator which is connected to the test specimen, stressing it in alternating bending. By substituting a sine-wave source for the random-noise generator, conventional constant-amplitude fatigue tests may be carried out in the same machine. Using 24 *ST* aluminium alloy specimens, the fatigue life at eight sine-wave stress levels and two random-noise levels was determined using five to seven specimens at each level. Mean and minimum *S*—*N* curves were drawn through the sine wave results, and with these, Miner's rule and the probability distribution of stress peak amplitudes in the noise wave form (as given by Rice[2]), the mean and minimum predicted fatigue life at the two noise levels could be calculated. These are compared with the measured fatigue lives in Table 1. It will be seen that the predicted life is longer than that found experimentally by a factor of 2–3·5. In the calculation of predicted lives, Miner's rule has been used in its most severe form, namely, that a given stress peak is counted as equivalent to a half-cycle of a sine wave of the same peak amplitude with zero mean load. It is known that other interpretations of Miner's rule lead to even longer predicted lives.

Table 1. COMPARISON OF PREDICTED AND EXPERIMENTAL FATIGUE LIVES UNDER RANDOM LOADING

	Average fatigue life in 'cycles'			Minimum life in 'cycles'		
	Experimental	Predicted	Ratio	Experimental	Predicted	Ratio
Noise 1	$2 \cdot 0 \times 10^6$	$6 \cdot 9 \times 10^6$	3·45	$8 \cdot 8 \times 10^5$	$3 \cdot 0 \times 10^6$	3·40
Level 2	$1 \cdot 15 \times 10^6$	$3 \cdot 4 \times 10^6$	2·96	$7 \cdot 3 \times 10^5$	$1 \cdot 5 \times 10^6$	2·06

Note: A maximum and a minimum of the random wave form is counted as one 'cycle'.

In effect, the motion of the specimen (and the corresponding stress produced) is an amplified version of the Brownian motion of the resonant system formed by the mass of the moving coil of the vibrator and the spring of the specimen. To produce the amplitudes used in these tests by thermal activation would require a temperature of 10^{17}° K. The contribution of the room-temperature Brownian vibrations of the system to the stress level is quite negligible, a rough calculation of the fatigue life under these stresses giving a life of $10^{10^{21}}$ sec.

Full details of this work will be published elsewhere. For permission to publish this communication we thank the Chief Scientist, Department of Supply.

Metal Ion Catalysis and Polarity of Environment in the Aerobic Oxidation of Unsaturated Fatty Acids

IT is frequently stated that the intense activity of certain metallic compounds as oxidation catalysts is a matter of great technological interest and that knowledge of how these compounds react is still obscure in many details[1]. The foundations of a better understanding of the mechanism of metal ion catalysis were laid by Haber and Weiss[2]. The most notable recent advances in this field were made by C. E. H. Bawn[3] and his school. It is now generally accepted that the aerobic oxidation of linoleic acid and its esters proceeds through a chain reaction with the free radicals $R\cdot$ and $RO_2^{\cdot}$ as chain carriers, namely:

$$R\cdot + O_2 \rightarrow RO_2^{\cdot} \quad (1)$$

$$RO_2^{\cdot} + RH \rightarrow ROOH + R\cdot \quad (2)$$

The most difficult aspect is the initial production of free radicals. It is this aspect which is most directly related to metal catalysis. The following heavy-metal stearates were prepared and their catalytic effect examined: cupric, ferric, (partially oxidized) ferrous, cobaltous, manganous, cerous, vanadyl, thallous and stannous stearates. The latter two were investigated with the object of determining whether two-electron transfer would be more efficient than one-electron transfer in the initiation process. In the polar solvents ethyl alcohol, ethyl acetate and ethyl caprylate, none of the heavy metal stearates had any appreciable catalytic activity at 25° C., approximately $0 \cdot 1\ M$ methyl linoleate (or linoleic acid) and a catalyst concentration equal to or less than $M/5{,}000$. In dilute benzene solutions, cobaltous, manganous and cerous stearates were the only active catalysts leading to hydroperoxide formation. At a catalyst concentration of $M/5{,}000$, 25° C. and $0 \cdot 1\ M$ methyl linoleate, the rates of formation of hydroperoxide were approximately seven, five and four milliequivalents methyl linoleate hydroperoxide per mole methyl linoleate per hour with cobaltous, manganous and cerous stearate, respectively. Cupric stearate did not catalyse the formation of hydroperoxide but appeared to be an active catalyst in its decomposition into unsaturated aldehydes and ketones. The activation energy of hydroperoxide formation catalysed by cobaltous stearate was determined as 20 k.cal.

An even more pronounced catalytic effect was obtained with some heavy-metal phthalocyanines and octamethyltetrazaporphins (conjugated macrocycles), which were readily measurable at 25° C. in dilute benzene solutions down to a catalyst concentration of $5 \times 10^{-8}\ M$ ([methyl linoleate] $= 0 \cdot 1\ M$). The observed rates of hydroperoxide formation with ferrous phthalocyanine, cobaltous phthalocyanine and cobaltous octamethyltetrazaporphin (these substances were kindly supplied by Dr. J. A. Elvidge, of the Imperial College of Science and Technology) were about two milliequivalents per mole methyl linoleate per hour, at 25° C., a catalyst concentration of $5 \times 10^{-7}\ M$ and a substrate concentration of $0 \cdot 1\ M$. This is ten times the rate of the (apparently) uncatalysed reaction under similar conditions.

The general rate law for the aerobic oxidation with the heavy-metal catalysts in organic solvents was established as:

$$\frac{d[ROOH]}{dt} = k[RH]\,[\text{catalyst}]$$

A kinetic analysis indicated that this rate equation would be compatible with the general scheme:

$$Co^{2+} + O_2 \rightleftharpoons Co^{2+}.O_2$$
$$Co^{2+}.O_2 + Co^{2+}(XH) \rightarrow Co^{2+} + Co^{3+}X^- + HO_2^{\cdot}$$

$HO_2^{\cdot}$ radicals thus formed would initiate the chain reaction (1) and (2). The direct formation of $HO_2^{\cdot}$ by the reaction $RH + O_2 \rightarrow R\cdot + HO_2^{\cdot}$ is very much slower, as the endothermicity of this reaction would exceed 40 k.cal.[4] (the reaction $H + O_2 \rightarrow HO_2^{\cdot}$ being exothermic to an extent of approximately 35 k.cal.). The existence of similar complexes with molecular oxygen was recently postulated by J. Weiss[5] and P. George[6] in the aerobic oxidation of ferrous ion in aqueous solution.

The solvent effect was studied quantitatively in a mixture of the polar nitrobenzene (dielectric constant 37) and the non-polar benzene (dielectric constant 2·29). The effect was of such magnitude that I consider it must be attributed to the formation of different co-ordination spheres, which would alter the oxidation-reduction potential and the affinity to oxygen of the heavy-metal catalyst. The magnitude of this effect is illustrated in Table 1.

Table 1. EXPERIMENTS (AT 25° C.) WITH VARYING NITROBENZENE CONCENTRATIONS IN BENZENE–NITROBENZENE MIXTURES AND BLUE (ANHYDROUS) COBALTOUS STEARATE AS CATALYST
Total volume, 7·5 ml., including 0·5 ml. methyl linoleate (0·202 *M*)
[Cobalt stearate] = 1·87 × 10^{-4} *M*

Nitrobenzene (Vol. per cent)	Molar ratio $(C_6H_6)/(C_6H_5NO_2)$	Rate of formation of the hydroperoxide (m.equiv./mole methyl linoleate/hr.)
0	—	14·4
25	3·47	13·4
30	2·70	12·3
35	2·14	7·6
40	1·74	3·88
45	1·42	1·86
50	1·16	0·68
75	0·385	Nil
100	—	indistinguishable from blank tests

When the logarithm of the rate of hydroperoxide formation was plotted against the logarithm of the molar ratio benzene : nitrobenzene, the curve obtained was nearly parallel to the abscissa axis at low nitrobenzene concentrations ($\leqslant$ 25 per cent) with a gradually increasing slope which reaches the limit of six at about 50 per cent nitrobenzene. This would be in accordance with expectation if, as we assume, the cobaltous stearate solvated by benzene is catalytically active whereas the nitrobenzene-solvated compound is inactive. The limit slope of six would imply an inner co-ordination sphere with six solvent molecules.

There is also a distinct solvent effect due to co-ordination with the metal phthalocyanine catalysts; however, this effect has not yet been studied quantitatively. It was observed that the heavy-metal complexes of conjugated macrocycles were not affected by the addition of malic acid. On the other hand, the catalytic effects of cobaltous and manganous stearate in benzene at a concentration of $M/5{,}000$ were quantitatively suppressed when malic acid was added at a molar ratio greater than 1 : 1. The catalytic activity of the heavy-metal porphin derivatives can be inhibited by the addition of free radical acceptors such as butylated hydroxy anisole, and in my experience even more effectively by quercetin and rhamnetin. The latter two substances merit more attention as efficient antioxidants.

The observations relating to the solvent effect (in the co-ordination sphere) have their practical counterpart in the storage of dehydrated food products, where oxidative rancidity abruptly sets in and becomes the decisive factor when the moisture concentration drops below a critical limit. This critical limit is connected, in my view, with the stage in dehydration in which the co-ordination spheres of trace metals would be affected.

Radioactivation analysis for trace metals (after pile irradiation at the Atomic Energy Research Establishment, Harwell) was carried out with crude lipids and purified methyl linoleate, and preliminary results indicate that even the trace-metal content of purified methyl linoleate is of an order of magnitude comparable with the concentrations in which catalytic effects with the heavy metal porphin derivatives were observed.

I wish to thank Miss M. R. Menzies for her assistance in the experimental work. A detailed account of this investigation will be published elsewhere.

Absorption Spectra arising from the Photolysis of Lead Tetramethyl

THE flash photolysis technique[1] has been used to examine the photochemical decomposition of lead tetramethyl. At an energy of 2,500 joules (50 μF.; 10 kV.) the decomposition of lead tetramethyl at pressures up to 12 mm. mercury was shown to be largely complete in 1·2 m.sec. after the initial light flash; this was the time for the reaction vessel to become opaque to light due to the deposition of a lead film. The contents of the quartz reaction vessel (volume 500 cm.^{3}, surface/volume = 1·6) were examined in this interval by passing a second light flash through the length (1 metre) of the vessel into a large Littrow (Hilger *E*1) spectrograph using a slit width of 0·02 mm.

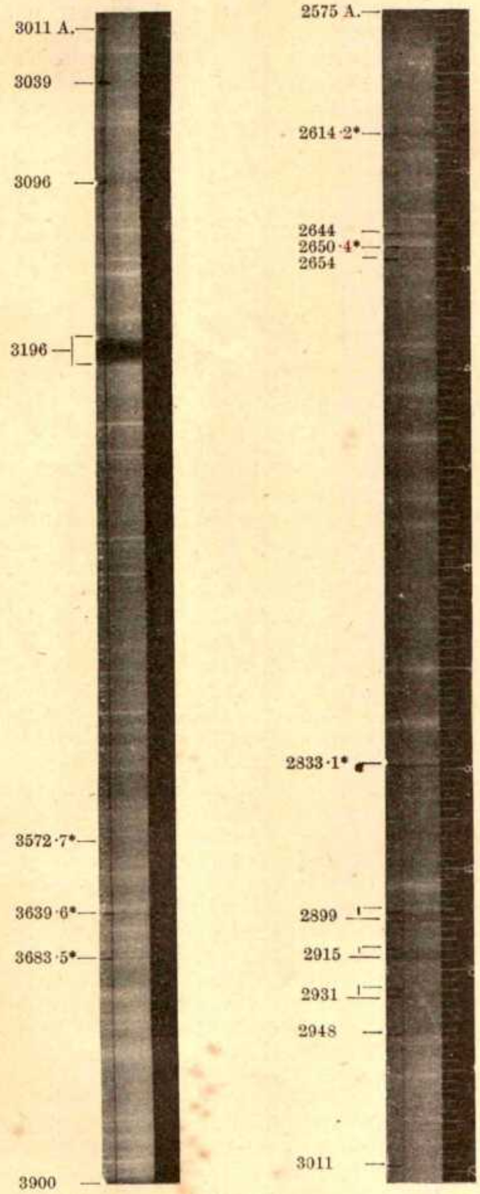
The absorption system shown (Fig. 1) was observed within 200 μsec. of the initial light flash. It consisted of a number of sharp lines due to atomic lead, together with a number of absorption regions not previously described (Table 1). The most prominent feature occurs with a maximum intensity at 3196 A. On exposures where this band is most intense, further bands are observed at shorter wave-lengths along with continuous absorption over the region below 4000 A. and increasing in intensity towards the ultra-violet region. In addition, a further series of bands, sharply degraded towards the violet and with heads at 2948, 2932, 2915 and 2899 A., have been seen on several occasions.

Analysis of the lead film on the walls of the vessel showed the photolysis to be very nearly quantitative. The efficiency of the photolysis lamp was determined by actinometry with uranyl oxalate[2]. At a vapour pressure of 12 mm. mercury the amount of lead deposited gave a quantum yield of about forty. The product gases on analysis were found to contain largely ethane (more than 90 per cent) and only a trace of methane. It would appear that a chain reaction, based on methyl radical attack on lead tetramethyl, is involved, in competition with the reaction of two methyl radicals, to give ethane. The abstraction of hydrogen by methyl to yield methane occurs to a very minor degree.

A sample of fully deuterated lead tetramethyl was prepared from methyl-d_3 bromide[3] via the Grignard compound and lead chloride. On photolysis it behaved in an identical manner, with no significant change in the absorption system. If the observed spectra are associated with the methyl radical, then deuteration may be expected to have a marked effect. Assuming the primary photolytic act is rupture of the lead–carbon bond:

$$Pb(CH_3)_4 \rightarrow CH_3^{\cdot} + {}^{\cdot}Pb(CH_3)_3$$

the lead trimethyl fragment may equally well give rise to the absorption system observed. Deuteration would in this case be expected to have little effect. Photolysis of lead tetra-ethyl also resulted in a deposit of lead on the reaction vessel; but only continuous absorption was observed from 4000 A. towards shorter wave-lengths.



* Atomic lead lines

Fig. 1

Table 1. ABSORPTION SPECTRA ARISING FROM THE PHOTOLYSIS OF LEAD TETRAMETHYL

λ (A.)	ν (cm.$^{-1}$)	$\Delta\nu$ (cm.$^{-1}$)	Intensity
3196	31,290	—	very strong
3096	32,300	1,010	weak
3039	32,910	610	very weak
3011	33,210	300	very weak
2948	33,920	710	weak
2931	34,120	200	weak
2915	34,305	185	weak
2899	34,490	185	weak

Photolysis of lead tetramethyl has also been attempted using a solution in *E.P.A.* glass[4] at 77° K. The apparatus closely resembled that described by Norman and Porter[5]. No absorption comparable to the system observed in the vapour phase has so far been detected. It is conceivable, in the light of recent work[6], that the absorption system observed arises from the lowest triplet level of ethane, which becomes populated through the excited ethane molecules formed by methyl radical combination. This work is still in progress and will be published in detail elsewhere.

We are indebted to the Chief Scientist, Department of Supply, Australia, for permission to publish this communication.

Mathematical Chemical Periodicity

LENGTHS of the periods and atomic numbers, L and Z, of a bidimensional continuous system based on the electronic structure of the elements, are numerical characteristics precisely definable, as functions of the principal and orbital quantum numbers n and l ($0 \leqslant l \leqslant n-1$), by the following general equations:

$$L = \tfrac{1}{2}[n + l + f(n + l)]^2 - E$$

$$Z = \binom{n + l + 2}{3} + \tfrac{1}{2}(n + l + 1)f(n + l) - 2l^2 - E$$

In these equations, the term of the periodical discontinuity, $f(n + l)$, as a quantum number function, is

$$\tfrac{1}{2}[1 - (-1)^{n+l}] \text{ or } \cos^2 \tfrac{1}{2}\pi(n + l + 1)$$

or an equivalent, and E is the number of missing electrons required for the completion of the subshell in which the given element occurs. For $E = 0$, one expresses the distances from the last inert gas (partial lengths of the periods) and atomic numbers, respectively, of the subshell closing elements, so that, in the particular case of $n = 1$, the length of the complete periods and the atomic numbers of the inert gases are found.

The two equations correspond to previously obtained combinational expressions[1] which here have been given a most convenient simplification. By placing the periodicity term $f(n + l)$ in algebraic form, L can reduce to the Tomkeieff's rule[2] ($E = 0$; $l = 1$), and Z becomes analogous to Hakala's law[3]. Thus they are shown to achieve wider generalization than the hitherto known formulæ.

Moreover, the close relationship established between L and Z constitutes synthetic mathematical evidence of a bidimensional double periodicity in the chemical table.

Thermodynamic Interpretation of the Eötvös Constant

EÖTVÖS[1], in 1886, proposed the following equation for liquids

$$\gamma(M\upsilon_{\mathrm{sp.}})^{2/3} = K_E\,(T_c - T) \qquad (1)$$

where γ is surface tension, M is molecular weight, $\upsilon_{\mathrm{sp.}}$ is specific volume and T_c is critical temperature, which is found to be strikingly valid over a wide range of temperature for most non-polar compounds. Even for polar compounds the equation is valid though to a more limited extent; but the value of the constant, K_E, is often very different from the usual value, 2·12. This empirical equation has been given some theoretical support (cf. Partington[2]). The purpose of the present communication is to point out a simple thermodynamic interpretation of the above equation.

Since the left-hand side of the equation is a free-energy term and the right-hand side is linear in T, its formal similarity with the standard thermodynamic equation, $\Delta F = \Delta H - T\Delta S$, is apparent. Based on this we can identify the Eötvös constant as the entropy of formation in proper units of $(M\upsilon_{\mathrm{sp.}})^{2/3}$ surface area starting from liquids in the interior. Since a mole of a liquid considered as a cube presents an area of any face equal to $(M\upsilon_{\mathrm{sp.}})^{2/3}$, and since this cube can be divided into $N^{1/3}$ such faces, the molar entropy is easily obtained by multiplying both sides of equation (1) by $N^{1/3}$. Converted into calories, we obtain the molar entropy of surface formation for non-polar compounds,

$$2{\cdot}018 \times K_E \text{ cal./deg.} = 4{\cdot}28 \text{ entropy units}$$

Thus we arrive at the interesting conclusion that the Eötvös constant is a measure of the entropy of formation of surface and the entropy change in bringing liquid molecules from the interior to the surface is the same for all non-polar liquids and nearly the same for all liquids, and is equal to 4·28 calories per degree per mole. In other words, the Eötvös equation is the liquid-surface analogue of Trouton's law relating to vaporization.

It seems plausible that this excess entropy on the surface is almost wholly configurational, arising out of increased symmetry in the interior of a liquid and the non-spherical shape of liquid molecules. This idea is supported by the fact that the corresponding entropy changes for alcohols are much lower, being 1·88 for methyl alcohol and 2·18 for ethyl alcohol. This loss of entropy for polar liquids is thus to be ascribed to the well-known orientation of such molecules on the interface. This also agrees with the observation that mercury ($K_E \simeq 1$), which presumably has more or less spherical molecules, has a lower Eötvös constant, and geometrically complicated molecules, for example, tripalmitin (K_E = 5·4), have higher Eötvös constants.

Conversely, a thermodynamic deduction of Eötvös equation from the above assumption, the temperature independence of ΔH, and the boundary condition of zero free-surface energy at the critical temperature, is simple and need not be elaborated here. The next step would be to investigate the possibility of deduction of the numerical value of K_E from statistical thermodynamics.

Oxidation-Reduction Potential of Modified Cytochrome *c*

THE presence of modified cytochrome *c* in the widely used Keilin and Hartree preparation was first reported by Margoliash[1]. Separation was effected by chromatography at *p*H 7·0 on a column of the resin 'Amberlite *IRC*-50'. Modified material was present to the extent of 10–25 per cent and was characterized by having a lowered enzymatic activity in the cytochrome oxidase (heart muscle) and succinic oxidase (kidney) systems but an increased rate of ascorbic acid oxidation. Visual spectroscopy, however, did not show any difference between this and other cytochrome *c* fractions. Evidence was presented that the modification was caused by the action of trichloracetic acid on cytochrome *c* during the extraction procedure.

We have recently compared[2] the E'_0 values at *p*H 6·4 and 25° C. of the usual Keilin and Hartree type preparation with cytochrome *c*, purified on a resin column, from both ox- and horse-heart muscle. It was suggested that the slightly higher value of the less pure samples (0·270 V.) compared with the resin-purified samples (0·255 V.) was due to the presence of modified cytochrome *c*. We have now determined the E'_0 value of this material as separated by the above procedure from ox-heart cytochrome *c* and find it to be 0·310 V. under the same conditions of *p*H and temperature.

In order to attempt its complete modification, a sample of ox-heart cytochrome *c* purified on a resin column was subjected to prolonged treatment with trichloracetic acid (2·5 per cent, 18 hr. at 25° C.), followed by dialysis against 0·5 per cent sodium chloride. The potential of the resulting pigment solution was found to be very close to the above value, namely, $E'_0 = 0{\cdot}308$ V. at pH 6·4 and 25° C. This material did not show any increased ascorbic acid oxidase effect over the values usually obtained for Keilin and Hartree preparations of cytochrome *c*. There was present, however, after the above dialysis, a small residue of cytochrome *c*-like material, soluble in dilute ammonium hydroxide. This had a sevenfold increase in catalytic effect on the oxidation of ascorbic acid. The potential of this residue has not as yet been determined. Absorption curves for these fractions, reduced with sodium dithionite, revealed band positions identical with those of resin-purified cytochrome *c*. However, differences in the degree of light absorption were observed, particularly on the longer wave-length slopes of the α-bands.

The increase in E'_0 value of cytochrome *c* on modification brings about what is almost certainly a critical shift of its position in the classical picture of stepwise tissue oxidation as proposed by Ball[3]. Although it is not yet possible to define the nature of such modification which results in an increase of just over 50 mV. in the potential-level, it is clear that the effect must be taken into account in assessing the results of studies involving the catalytic functions of cytochrome *c*.

Tocopherol Content of Heart-muscle Preparations

THE possible role of vitamin E in respiratory enzyme systems has often been suggested; but supporting evidence of the actual presence of vitamin E in active enzyme preparations has not been published. We have now found appreciable amounts in heart sarcosomal (mitochondrial) fragments (Keilin and Hartree heart-muscle preparation).

Sarcosomal fragments prepared by one of us (E. C. S.) in Cambridge were analysed by Dr. K. L. Blaxter and Miss R. F. McGill at the Hannah Dairy Research Institute, Scotland. The first preparation showed no tocopherol activity measured as the free alcohol or its esters. When, with later preparations, the non-saponifiable material from alcoholic extracts of dried sarcosomal fragments was treated with stannous chloride in dioxane in order to reduce any oxidized tocopherol which might be present, an appreciable amount of material reducing ferric chloride was obtained. This behaved like α-tocopherol on reversed-phase chromatography[1]. In view of these results, a more detailed investigation was made in the Amsterdam laboratory.

The freeze-dried preparation of sarcosomal fragments (4 gm., containing 2·40 gm. protein) was extracted with dry alcohol containing pyrogallol, and the extract saponified. The ethanolic solution of the non-saponifiable fraction was refluxed with ascorbic acid in strong hydrochloric acid to convert any tocopherylquinone to tocopherol. After removal of sterols by treatment with methanol, and of carotenoids by passage through a column of 'Floridin *XS* Earth', the ethanolic solution containing the tocopherol was subjected to the paper-chromatography procedure of Green *et al.*[2]. A spot was obtained of an R_F a little more than that of a pure solution of α-tocopherol run simultaneously (Fig. 1). When, however, α-tocopherol was added to the alcoholic solution derived from the heart-muscle preparation, one spot only was obtained. No β- or γ-tocopherol, which is readily separated from α-tocopherol by this procedure, was detected.

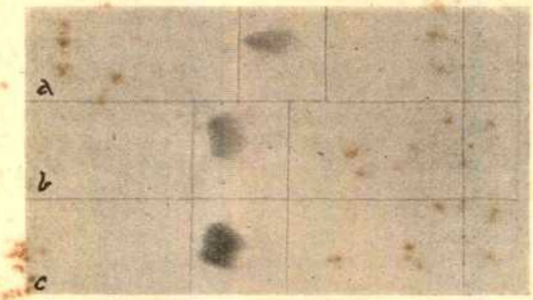

Fig. 1. Paper chromatogram, made according to the procedure of Green *et al.* (ref. 2): *a*, pure α-tocopherol (20γ); *b*, purified extract from heart sarcosomal fragments (0·02 ml.); *c*, α-tocopherol (20γ)+the purified extract (0·02 ml.). The papers were sprayed with ammoniacal silver nitrate, and the excess reagent removed with sodium thiosulphate

The identity of the material giving the spot on the chromatogram with α-tocopherol was confirmed by extraction with ethanol and oxidation with ferric chloride. The oxidation products were extracted with petroleum ether, and after evaporation dissolved in ethanol. This solution showed the typical two-banded spectrum obtained with tocopherol oxidized under these conditions. The positions of the bands (262 mμ and 269 mμ) coincided exactly with those ascribed to toco-red[3].

The amount of α-tocopherol was determined by extraction of the area of the spots with warm ethanol, followed by estimation of the tocopherol content by the method of Emmerie, using the spot with added α-tocopherol as an 'internal standard'. The amount found was 1·1 μmole per gm. protein. This value refers to α-tocopherol plus its oxidation products (for example, α-tocopheroxide or α-tocopherylquinone) which might be present in the heart-muscle preparation. It does not, however, include any tocopherylhydroquinone, which would probably not be extracted into the non-saponifiable fraction. It is hoped that further investigations will reveal the form of tocopherol which is present in the heart-muscle preparation.

Vitamin E is the only fat-soluble vitamin present in the heart-muscle preparation in appreciable amounts. The preparation contains less than 0·01 μmole vitamin K/gm. protein (analysis kindly carried out by Miss I. Kruse, of the Department of Biochemistry and Nutrition, Danish Polytechnic Institute, Copenhagen), less than 0·03 μmole vitamin D/gm. protein (analysis kindly carried out by Dr. E. Kodicek, of the Dunn Nutritional Laboratory, Cambridge) and less than 0·01 μmole vitamin A/gm. protein (our own analysis). These values are so low that it is unlikely that any of these vitamins are involved in the non-phosphorylating respiratory chain of the sarcosomal fragments.

On the other hand, the amount of α-tocopherol (1·1 μmole/gm. protein) is of the same order of magnitude as of known components of the chain (for example, cytochrome *c*, 0·8 μmole/gm. protein). Although the presence of tocopherol in the preparation does not prove that it is involved in the respiratory chain, the actual amount found makes this not unlikely, especially when taken in conjunction with the important experiments of Nason and Lehmann[4]. These authors have shown that added vitamin E activates the reduced diphosphopyridine nucleotide oxidase activity of a particulate preparation from rat skeletal muscle, especially after extraction of the preparation with *iso*-octane. Although Nason and Lehmann were able to activate the enzyme preparation by the lipid present in the *iso*-octane extract, they were unable to detect vitamin E in the extract. We have been able to show the presence of α-tocopherol (or its oxidation products) in *iso*-octane extracts of suspensions of the heart-muscle preparation.

We are grateful to Dr. G. Baxter, Distillation Products, for supplying samples of pure tocopherols.

Note added in proof (June 1). Nason *et al.*[5] have recently shown that the reduced diphosphopyridine nucleotide oxidase system in the rat muscle preparation could be reactivated by high concentrations of crystalline serum albumin, as well as by α-tocopherol. Albumin, previously extracted with *iso*-octane, was ineffective. We have now found that crystalline bovine serum albumin (Armour) contains 0·056 μmole α-tocopherol/gm. protein.

Pharmacological Action of Rauwolscine

Rauwolscine (kindly supplied by Mrs. A. Chatterjee, University College of Science and Technology, Calcutta), an alkaloid of *Rauwolfia canescens* Linn.[1], has been found to be a potent adrenolytic compound[2,3]. It has further been shown to be α-yohimbine[4]. Yohimbine is an adrenergic blocking alkaloid; but it produces certain other effects, such as stimulation of the central nervous system, local anæsthesia and vague aphrodisiac activity[5], which have precluded its use in clinical practice. No detailed report has appeared so far of any investigation of these properties; we have therefore examined these pharmacological actions of rauwolscine with the following results.

(1) A 2 per cent solution of rauwolscine giving a visible film on the guinea pig cornea produces complete surface anæsthesia starting 5–7 min. after instillation and lasting up to 15–20 min.

(2) 0·25 c.c. of a 0·2–2·0 per cent solution of rauwolscine in normal saline (*p*H 5·2–5·5) produced local anæsthesia in guinea pigs as tested by the method of Bülbring and Wajda[6], and lasts more than 2 hr. This, however, appears to cause local damage to the tissues.

(3) 10–20 mgm./kgm. injected intraperitoneally into guinea pigs produces signs of psychic excitement and erection in the male animals. The animals become highly excitable and restless.

(4) 25 mgm./kgm. injected intraperitoneally in rats lowers the convulsant threshold level of metrazol.

(5) 12–15 mgm./kgm. injected intravenously in rabbits produces sudden clonic convulsions lasting 2–3 min., accompanied by increased respiratory-rate and followed by sexual excitement. When injected intraperitoneally, 20 mgm./kgm. produces no convulsions but other effects; for example, increased motor activity, psychic excitement and increased respiration appear in 5–10 min.

A comparison of the adrenergic blocking activity of rauwolscine with 2-benzyl-imidazoline hydrochloride ('Priscol', Ciba), an agent recommended in the treatment of peripheral vascular diseases on the basis of its adrenolytic activity, was also undertaken. This study was carried out on the isolated guinea pig seminal vesicle following the method described by Stone *et al.*[7]. In concentrations of 1 in 250,000 to 1 in 80,000, the two compounds show nearly equivalent adrenolytic activity; but in higher concentrations, for example, 1 in 60,000 to 1 in 50,000, tolazoline produces only 40–50 per cent adrenolysis whereas rauwolscine produces 81–93 per cent.

These studies thus indicate that in low concentrations rauwolscine possesses marked adrenolytic activity; but in relatively higher dosages it has some of the side-effects of yohimbine. Detailed comparison between rauwolscine and yohimbine and other adrenolytic compounds is now being carried out to determine the clinical potentialities of rauwolscine.

Assimilation of Berberine by Bacteria

Berberine hydrochloride has been reported to be toxic in weak concentrations against some species of bacteria[1] and some fungi[2]. Recent studies in this laboratory have shown that several species of bacteria assimilate the alkaloid from media provided with suitable nutrients, as well as from extracts of plants containing berberine and chelidoxanthine.

Some of the bacteria tested are sensitive to berberine and do not grow at a concentration of the hydrochloride as low as 0·0025 per cent; others resist and are able to absorb it from media containing as much as 2 per cent. The bacteria, during growth, absorb (assimilate) the pure alkaloid into their protoplasm but do not use it either as a source of carbon or of nitrogen. The evidence for absorption is found by the bright yellow fluorescence of the cells in ultra-violet light, of the same fluorescence as that of the alkaloid, whereas there is only minimal absorption of washed resting cells in saline or nutrient-free media.

The cells, moreover, which have absorbed the alkaloid, when washed and used as a source of organic nitrogen in an otherwise berberine-free nutrient medium, serve to supply other bacteria with nitrogen. The bacteria that utilize the nitrogen of 'berberinized' cells may be the same species that provided the nitrogen, or other species. Evidence of this 'secondary assimilation' is found both in the yellow fluorescence of the second-culture cells, and in the clear zones of proteolysis surrounding their colonies on agar plates.

Flight-muscle Changes during Adult Life in a Scolytid Beetle

IT has long been known that in ant and termite queens the wings are lost and the flight muscles degenerate after the mating flight. Recently, flight-muscle degeneration has been reported in aphids[1] and mosquitoes[2], although in the latter group further studies appear to be desirable[3]. In the Coleoptera, protection of the posterior membranous wings, when at rest, by the tough anterior wings or elytra makes possible utilization of confined habitats, such as burrows of various types, which are unavailable to many other winged insects. Whether or not such protection is related to loss or reduction of wings, the fact remains that in several families of this group flightless species have evolved[4]. Most of these species have membranous wings greatly reduced in size; but small wing muscles and other morphological indications of loss of the ability to fly have been noted in some instances where wings are normal. Certain species are variable with respect to capacity for flight, some individuals being able to fly although others are not. A seasonal change in flight muscles has been noted in a weevil, and evidence suggests that such a change occurs in certain water beetles.

I have recently investigated the capacity and inclination to fly in a member of the Scolytidae, the ambrosia beetle, *Trypodendron lineatum* (Oliv.). Individuals have been flown on fixed mounts or flight mills and have been tossed into the air at various times during their adult life. Beetles taken in the spring often show considerable capacity for flight. Some will fly for several (up to eight) hours continuously on flight mills or on fixed mounts. Individuals taken in flight will fly immediately when tossed; but those removed from well-established galleries will not.

In this species the young adults, after a feeding period within the galleries, generally fly from the brood logs to their over-wintering site and again the following spring when they carry out their first attack. The parent adults also fly from the brood logs in the first season and may attack other material then or in the following season, producing another brood in either case. Young or parent adults taken from galleries before natural emergence usually will not fly when tossed. They take to flight, however, after a period of time at room temperature.

Dissection of parent adults of either sex removed from galleries containing eggs or larvæ reveals that the large indirect flight muscles are greatly reduced in size, to such an extent that they have almost disappeared. In the females, the much enlarged ovaries project forward into space normally occupied by these muscles. In both sexes the ventriculus is enlarged at this time and also fills part of this space. Parent adults taken just before they emerge naturally from galleries, however, have large flight muscles which appear normal. We thus have an example of temporary but marked reduction in size of flight muscles during brood establishment, followed by return to normal size and, apparently, function.

The reduction of flight muscles occurs at a time of adult activity without feeding and, consequently, of depletion of metabolic reserves. Later, the beetles feed intensively within the galleries, and this permits a building up of these reserves and presumably affects the redevelopment of the flight muscles. The details of the changes in these muscles, however, remain to be worked out.

The flightless period during adult life has ecological significance in that beetles cannot abandon their galleries by flight during this time. It seems likely that the phenomenon occurs in other members of the Scolytidae also, as the pattern of life within the entire family is essentially similar and involves long periods within plant tissue preceded by, or alternating with, relatively brief periods of flight. In any event *Trypodendron* shows an interesting compromise, within the Coleoptera, between the need for sustained flight at certain times and the occurrence of long periods of adult activity in burrowing and establishing a brood in a protected and confined habitat, where flight is not necessary.

Heat Increments of Feeding in Ruminants

IN ruminants the heat losses associated with carbohydrate dissimilation amount to 30–70 k.cal./100 k.cal. carbohydrate digested[1], whereas in man such losses are only 5–7 k.cal./100 k.cal.[2]. In calorimetric experiments with fasted sheep, we have found that the steam-volatile fatty acids which are the major end-products of rumen fermentation of carbohydrate produce a greater heat increment than does glucose given under similar conditions, precautions having been taken to minimize bacterial fermentation of the sugar. Furthermore, in starved animals, and also in those receiving food, the energy-loss as heat is considerably greater for acetic acid than for propionic or butyric acids.

A typical starvation experiment was as follows. A fasted sheep, with a permanent rumen fistula, was confined in a respiration chamber[3], and physiological saline (6,570 ml./24 hr.) was dripped into its rumen at a constant rate. Oxygen consumption, carbon dioxide and methane production, urinary nitrogen and ketone body-excretion were measured

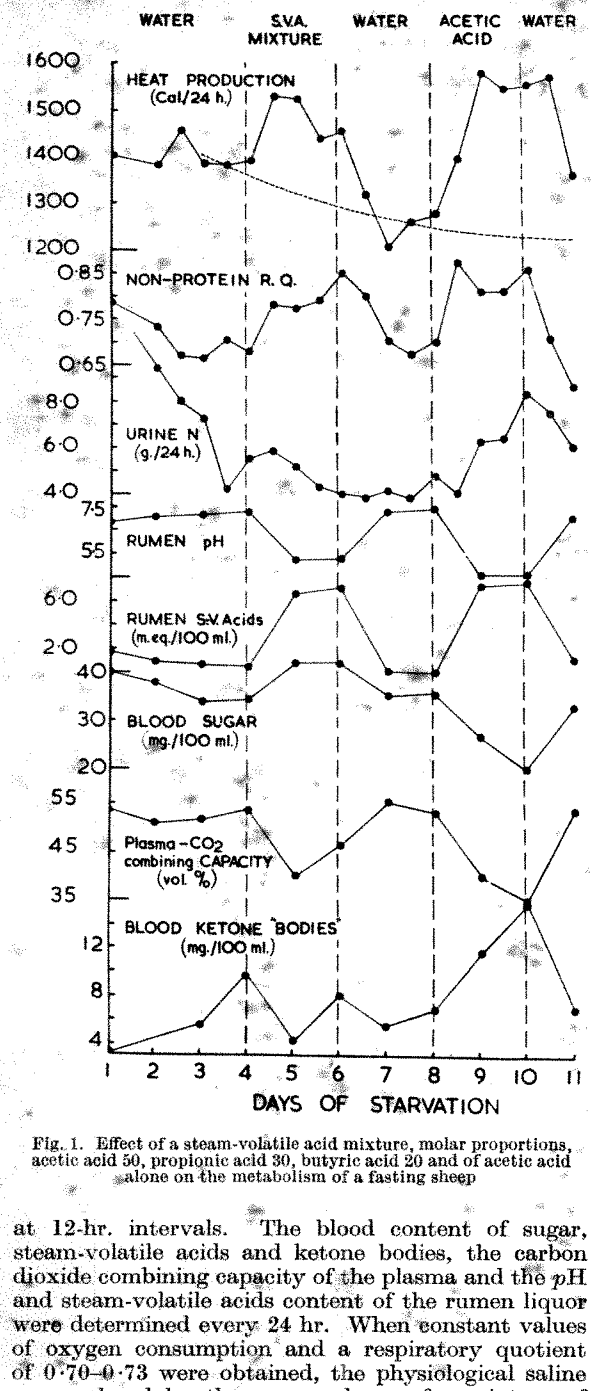

Fig. 1. Effect of a steam-volatile acid mixture, molar proportions, acetic acid 50, propionic acid 30, butyric acid 20 and of acetic acid alone on the metabolism of a fasting sheep

at 12-hr. intervals. The blood content of sugar, steam-volatile acids and ketone bodies, the carbon dioxide combining capacity of the plasma and the *p*H and steam-volatile acids content of the rumen liquor were determined every 24 hr. When constant values of oxygen consumption and a respiratory quotient of 0·70–0·73 were obtained, the physiological saline was replaced by the same volume of a mixture of acetic, propionic and butyric acids in the molar proportions 50 : 30 : 20, to supply 1,100 k.cal. in 24 hr. The acid mixture contained the same amount of modified saline as before and was given for 48 hr. The animal then received water and saline for a further 48 hr., followed by a similar period during which it received an acetic acid solution supplying 700 k.cal./24 hr. The sheep was then returned to the saline regimen for a final 24-hr. period. The results are summarized in Fig. 1.

The mixed steam-volatile acids did not depress the rumen *p*H beyond the limit of the normal physiological range, although initially a slight systemic acidosis developed. There was an appreciable rise in blood glucose. From the increase in oxygen consumption and carbon dioxide production, and from the elimination of urinary nitrogen, the heat increment, that is, the extra heat lost on giving the mixture of acids expressed as a percentage of the total calorie content of the acids, was calculated to be 16 per cent.

During the administration of acetic acid the very marked rise in heat production that occurred amounted to between 46 and 50 per cent of the energy input. A systemic acidosis developed with the accumulation of volatile acids in the peripheral blood. A decline in blood sugar, an increased excretion of nitrogen in the urine and a ketonæmia also occurred.

Further experiments have confirmed the high (44–50 per cent) heat losses associated with dissimilation of acetic acid in the fasting sheep ; in the fed animal even higher heat losses (56–61 per cent) occur. These results suggest that the efficiency of free-energy capture in acetic acid dissimilation is very appreciably lower than that from hexose or from butyric and propionic acids. It should be pointed out that in these experiments the acids have been given at constant slow rates in amounts which may be regarded as physiological.

The results may do much to explain the fact that heat increments in ruminants vary with the fibre content of the food[1], since the proportion of acetic acid in the fermentation products increases with increasing fibre content[4]. Whether measurements *in vitro* of the molar proportions of the steam-volatile acids formed when different foodstuffs are fermented by mixed rumen organisms will permit prediction of the heat increments of rations remains to be seen.

Invagination as an Organic Process

It may be worth while pointing out that invagination is an organic process which is now known to occur at three levels of organic structure : (1) invagination of cells in the process of gastrulation, (2) invagination or ingrowth of furrows in the process of wall formation in the pollen mother cells of certain angiosperms, (3) ingrowth of dissepiments in the development of mitochondria in animal cells. The process thus applies to cell masses in gastrulation, to cell-wall formation in certain pollen mother cells, and to an organelle in the cytoplasm of animal cells.

There appears to be nothing in the inorganic world which corresponds to this organic process. On the contrary, the growth in length of plant cell walls through intussusception under the influence of auxin is followed by the apposition of thickening layers of fibrils in a manner resembling crystal growth ; but the regularity of the microfibrillæ as seen under the electron microscope never quite equals that of the molecules in a crystal.

Gastrulation of the blastula by invagination to form the archenteron is too well known to need comment. It occurs in invertebrate embryos, amphibians and reptiles, and is recognized in modified form in birds and mammals. The forces and processes inducing it have been much studied by experimental embryologists.

Gastrulation may be said to result from unequal mitotic-rates in cells of the blastula having different sizes, contents and potentialities, especially those of the organizer at the dorsal lip of the blastopore, where a meristem gives rise to both ectoderm and endoderm cells. The fundamental nature of this process arises not only from its widespread occurrence in animal embryology but also from the fact that in totipotent eggs single blastomeres of the 16- or 32-cell stage of the blastula are capable of forming embryos which undergo gastrulation.

No corresponding process occurs in plants at this level of structure, except in the reproductive stages of certain algae, such as *Volvox*[1]. Here the blastula-like hollow sphere of cells has an opening which corresponds to the blastopore. The latter opens out and the whole structure evaginates, turning itself inside out—a process in some respects the reverse of gastrulation.

The formation of cell walls by invagination or furrowing, thus cutting the pollen mother cell into four parts, was clearly described in *Lathraea*[2], in a paper which has been generally overlooked. Narrow, finger-like, hollow processes grow in from four points on the periphery of the mother cell and finally meet in the centre. As these furrows advance a delicate cell wall is secreted or laid down in their hollow interior. The same or a closely similar process has been described in the pollen mother cells of certain other plants, although in many Angiosperms the tetrad walls are laid down in a very different way, on the mitotic spindles. This furrowing process is very similar to the cell division by constriction which occurs in the cleavage stages of animal embryos. The only difference is in the narrower form of the cleavage furrows as described above in pollen mother cells.

The third form of invagination, in animal mitochondria, is most unexpected and has only come to light through the use of the electron microscope. Here again, thin, hollow, finger-like processes grow inward from the margin of the elongated mitochondrion. By reaching the opposite wall they divide the organelle into a series of compartments. This structure is now known in the mitochondria of mammals[3], invertebrates[4] (including insects), and Protozoa[5]. The universality of the septation of true mitochondria in animal cells seems to indicate that this organelle developed in animal cytoplasm at the unicell stage of evolution. Cytoplasmic granules which do not show septation should obviously be classed among the microsomes, though some of the latter may be preseptation stages of mitochondria. Thus the 'mitochondria' of bacterial cells are perhaps better considered as microsomes.

Pelade[3,6], in describing the mitochondria of rat liver, kidney tubules and striated muscle under the electron microscope, finds them surrounded by a membrane which appears double. Into the interior protrude ridges (cristae mitochondriales) which appear as parallel folds (c. 20 mμ in thickness) arising from the inner membrane. Pelade compares them with the villi of the intestinal mucosa. He suggests that the cristae serve to localize the oxidative enzymes known to be present in mitochondria. Sjöstrand[7] also describes the mitochondria as surrounded by a double membrane, the many cross-partitions also having a double membrane. In mouse kidney, Sjöstrand and Rhodin[8] find these cross-partitions to be double, the border membranes separated by a narrow space. Sjöstrand and Hanzon[9] find a similar structure in mouse pancreas cells, the double-edged membranes or plates being *c.* 170 A. thick.

From further evidence, Frey-Wyssling[10] concludes that the cristae arise as invaginations of the inner membrane, each invagination becoming a flat disk which takes the shape of a flattened bladder with a narrow neck. They are therefore true submicroscopic invaginations, as their double walls indicate. There is still, however, difference of opinion as to whether an osmotic membrane surrounds the mitochondrion[11,12]. Harman and Kitiyakara[13] find in the mitochondria of pigeon skeletal muscle no semi-permeable membrane but a gel-like internal matrix between the cristae.

It has been held that mitochondria undergo not only transverse but also longitudinal division. It is difficult to see how the latter could take place in a structure already septate.

The close relation of plant mitochondria to chloroplasts necessitates a different structure in them. Instead of septation the proplastid, according to the recent account of Mühlethaler[14], contains a single granum from which lamellæ grow out through the stroma of the plastid. This outgrowth again is an organic, in contradistinction to an inorganic, process, showing that even at submicroscopic levels purely physical (crystallizing) forces are not the only ones concerned in molecular alignments.

A Rapid Method for Permanent Aceto-Carmine Squash Preparations

Most methods of preserving chromosome configurations prepared by aceto-carmine squash techniques involve either a somewhat lengthy procedure by which the tissues come to be mounted in balsam or 'Euparal', or else an effective sealing-off of the aqueous medium by ringing with 'Vaseline' or other impervious material. The former methods are time-consuming, and there is a risk that cells may become distorted in the process. The latter procedures are often unsatisfactory over long periods and frequently necessitate storage in the refrigerator to prevent darkening and deterioration.

The following technique is remarkably simple and effective. Freshly prepared squashes are thoroughly irrigated with 45 per cent acetic acid to remove all excess stain. (This may be facilitated by wiping the edges of the coverglass, holding the latter securely at one corner.) A small drop of 10 per cent glycerine in 45 per cent acetic acid is then placed at the margin of the coverglass and allowed to flow under as the aqueous portion evaporates. Should bubbles appear after a day or two, another drop of the glycerine solution may be added.

Advantages of the method are: (1) It is very rapid. (2) It is truly permanent. Even though large areas under the coverglass become filled with air, the glycerine remains in the individual cells and prevents their distortion. (3) Should darkening occur, 45 per cent acetic acid may be added at the edge of the coverglass and the slide gently heated until correct differentiation is achieved. (4) If care is exercised to avoid adding too much glycerine, the coverglass is held so firmly in place (by the evaporation of the acetic acid) that it may be rubbed quite vigorously without danger of displacement when removing oil or dirt. (5) The glycerine is so inert and non-volatile that there is no problem of artefact formation or of the medium becoming discoloured or brittle. (6) The refractive index of glycerine is sufficiently close to that of balsam to give a good microscopic image. It has the further advantage of complete transparency to ultra-violet and near-ultra-violet light.

The method may be extended to other types of microscopic preparation where the final mounting medium is soluble in water, and where pressure of the coverglass is not deleterious or the tissue too thick. It has been used for many years in this Department, for example, for preparations of macerated cells.

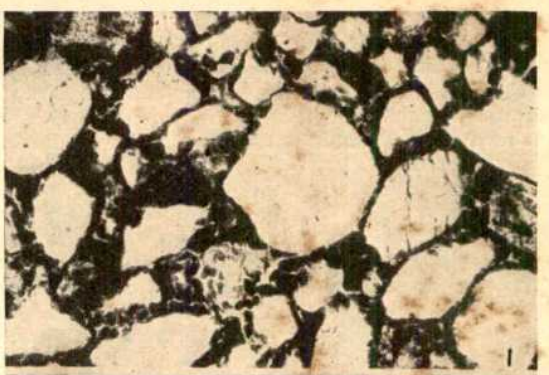
Sectioning of Soil

MANY workers interested in soil microbiology or soil structure have attempted to impregnate soil with materials such as balsam in the hope that the soil could be hardened sufficiently to enable sections to be prepared by normal geological techniques. Few of these attempts met with much success. Kubiena[1] made considerable progress by introducing the use of a thermolabile plastic material, and was able to prepare sections showing the soil structure in many different soil types. However, Kubiena's technique does not seem to have given satisfactory results in the hands of other workers. Haarløv and Weis-Fogh[2] have developed a method for sectioning litter, using a hardened agar, but their method is unsatisfactory for mineral soil. More recently, Alexander and Jackson[3] have described the use of a marco-resin for impregnating the soil and preparing thin sections.

We have found that the procedure can be greatly simplified by using a 'Bakelite' polymeric resin *S.R.* 17497 and its associated catalyst and accelerator. The resin has a low viscosity, good wetting powers and sets at room temperature in 12–24 hr. to a hard water-white solid which can be ground with carborundum. The setting time can be controlled by varying the amounts of catalyst and accelerator.



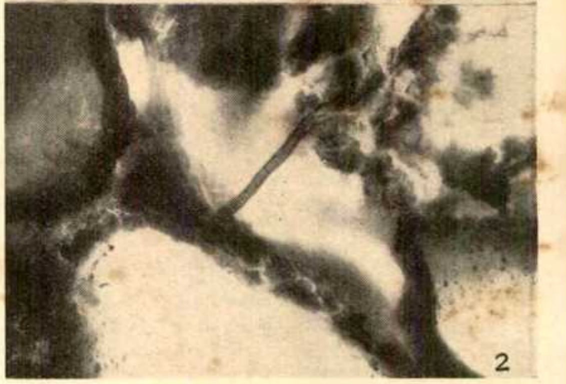


Fig. 1. B_1 horizon of a podzol, sand grains cemented with sesquioxide and humus. × 60 approx.

Fig. 2. Fungal hypha in pore space of the B_1 horizon. × 300 approx.

A piece of air-dry soil about 2 cm. × 1·5 cm. × 0·5 cm. is placed in a pool of resin on a slide. The resin readily fills the soil spaces, and after it has set the soil can be treated like a rock chip. The upper surface is ground to give the maximum surface area and then polished. The soil is taken off the slide and remounted in resin, polished side downwards. After the resin has set, the soil is ground down to a thin film and polished. Finally, it is mounted in resin under a cover glass. 'Carborundum' 280-grade has been used for the grinding and a No. 200 hone for polishing. Sections 50–60μ thick have been found suitable for the examination of the fungi in soil.

This method has been developed primarily for the study of fungal hyphæ in the soil; but mites, nematodes and thecate amœbæ have also been examined.

Fig. 1 shows the general distribution of quartz grains and the cementing sesquioxide and humus in the B_1 horizon of a podzol. In Fig. 2 a fungal hypha can be seen passing from the humus coating on one sand grain across the soil pore to another grain.

We would like to thank Messrs. Bakelite, Ltd., Redfern Road Works, Tyseley, Birmingham 11, for their kindness in supplying samples of resin.

FORTHCOMING EVENTS

Monday, June 25

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture heatre of the Science Museum, Exhibition Road, London, S.W.7), 5.30 p.m.—Prof. I. Bernard Cohen: "Some Aspects of the Aims, ethods and Influence of Newton's Scientific Work".

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at the Geogical Society, Burlington House, Piccadilly, London, W.1), at 30 p.m.—Dr. R. L. Metcalf (University of California): "Physicohemical Approach to Insecticide Action".

Thursday, June 28

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), t 4.30 p.m.—Sir K. S. Krishnan, F.R.S.: "The National Physical aboratory of India"

Thursday, June 28—Saturday, June 30

BIOCHEMICAL SOCIETY (joint meeting with the SCANDINAVIAN IOCHEMICAL SOCIETIES, in the Department of Biochemistry, Tennis ourt Road, Cambridge), at 2 p.m.—Scientific Papers.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or efore the dates mentioned:

ASSISTANT, Grade B (graduate in mathematics, engineering or ience, with teaching or industrial experience) IN THE DEPARTMENT F MATHEMATICS—The Registrar, College of Technology and Comerce, The Newarke, Leicester (June 26).

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours egree in mathematics and physics, or equivalent qualifications, postraduate research experience, and preferably with a knowledge of the heory of the outer layers of a star and experience in stellar spectroscopy r photoelectric photometry), at the Royal Greenwich Observatory, Herstmonceux, Sussex, to take charge of the department conducting strophysical work (as distinct from astrometric and solar work)—The Secretary, Civil Service Commission, Scientific Branch, 30 Old Burlngton Street, London, W.1, quoting S.4599/56/7 (June 29).

LECTURER IN THEORETICAL CHEMISTRY—The Registrar, University College of North Staffordshire, Keele, Staffs (June 30).

LECTURER IN PHYSICS; ASSISTANT LECTURER IN CHEMISTRY; ASSISTANT LECTURER IN PHYSICS; and SENIOR LECTURERS (3) IN PHYSICS, at the Royal Technical College of East Africa—The Secretary, Advisory Committee on Colonial Colleges, 1 Woburn Square, London, W.C.1 (June 30).

RESEARCH ASSISTANT IN THE DEPARTMENT OF PHYSICS, to work on atmospheric electricity—The Secretary, The University, 38 North Bailey, Durham (June 30).

BENGER RESEARCH FELLOW (graduate in medicine or science (including pharmacy)) IN PHARMACOLOGY—The Registrar, The University, Manchester 13 (July 1).

PRINCIPAL LECTURER IN APPLIED MECHANICS at the Royal Naval College, Greenwich—The Secretary, Civil Service Commission, Burington Gardens, London, W.1, quoting 4600/56/8 (July 2).

SOIL ANALYST (with a degree or equivalent qualification in chemistry and at least two years subsequent experience), at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 3).

CHEMIST (with an honours degree in chemistry or chemical engineerng, or A.R.I.C., or equivalent qualifications) with the Ministry of Supply at Harefield, Middlesex, to assist in the technical direction of inspection of non-metallic aero materials, for example, metal–metal adhesives, windscreen glass, general chemicals and packaging materials, and to supervise all analyses, including spectrographic—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.388/6A (July 7)

RESEARCH ASSISTANT IN THE DEPARTMENT OF PURE MATHEMATICS—The Registrar, The University, Liverpool (July 7).

SCIENTIFIC OFFICER (honours graduate) IN THE ENTOMOLOGY SECTION, for ecological and population studies of soil pests as affected by insecticides—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (July 7).

LECTURER IN ELECTRICAL ENGINEERING; LECTURER IN CIVIL ENGINEERING; and a LECTURER IN MECHANICAL ENGINEERING—The Assistant Secretary, The University, Edinburgh (July 9).

LECTURER or ASSISTANT LECTURER IN ZOOLOGY—The Registrar, The University, Manchester 13 (July 9)

LECTURER (preferably with a knowledge of some aspect of nuclear engineering) IN ENGINEERING (Mechanical)—The Registrar, The University, Manchester 13 (July 9).

LECTURER IN GEOLOGY—Head of the Department of Geology, Imperial College, London, S.W.7 (July 10).

SCIENTIFIC TECHNICAL OFFICERS (with physics qualifications, preferably graduate), for research teams working on problems in classical physics, heat transfer and mechanical properties of materials and compacts for the preparation of special fuels from coal—The National Coal Board, Coal Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting SS/304 (July 10)

ASSISTANT IN AERODYNAMICS—The Secretary of University Court, The University, Glasgow (July 14).

ASSISTANT IN GEOGRAPHY—The Secretary of University Court, The University, Glasgow (July 14).

ASSISTANT LECTURER (TAXONOMIST) IN THE DEPARTMENT OF BOTANY—The Registrar, University College of Wales, Aberystwyth (July 14).

DEMONSTRATORS (2) IN PHYSICS—The Registrar, College of Technology, Manchester 1 (July 14).

LECTURER IN THE DEPARTMENT OF NATURAL PHILOSOPHY—The Secretary, The University, Edinburgh (July 14).

CHAIR OF PHYSICS—The Registrar, The University, Birmingham 15 (July 15).

CHAIR OF PHYSIOLOGY at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 15).

LECTURER (with a good honour degree, including heavy current subjects, together with reasonable industrial and teaching experience, and preferably with experience with any of the following: high tension testing; modern servo-mechanisms; heavy current analogue computers) IN ELECTRICAL ENGINEERING—The Secretary and Registrar, The University, Southampton (July 15).

TUTORIAL RESEARCH STUDENT IN MATHEMATICS (Pure or Applied)—The Principal, Royal Holloway College, Englefield Green, Surrey (July 21).

LECTURER (with qualifications in pure mathematics or applied mathematics) IN MATHEMATICS—The Registrar (Room 9 O.R.B.), The University, Reading (July 23)

LECTURER (with training or experience in one of the following fields: (a) hydraulics; (b) aerodynamics; or (c) hydrodynamics) IN THE DEPARTMENT OF FLUID MECHANICS—The Registrar, The University, Liverpool (July 23).

SENIOR LECTURER IN THE DEPARTMENT OF ELECTRONIC ENGINEERING—The Registrar, The University, Liverpool (July 28).

CHAIR OF PHYSICS at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31).

LECTURER IN THE DEPARTMENT OF MATHEMATICS at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31).

LECTURER (preferably with a special interest in the history and philosophy of science) IN PHILOSOPHY at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31).

SENIOR LECTURER (highly qualified in statistical theory and widely experienced in the application of statistics to practical problems) IN STATISTICS, at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, July 31).

ASSISTANT (with a degree in science, preferably honours) IN THE CHEMISTRY DEPARTMENT at Auchincruive, Ayr, for work relating to the spectrographic analysis of agricultural materials—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (August 10).

PROFESSOR OF EDUCATION and HEAD OF THE DEPARTMENT OF EDUCATION—The Registrar, The University, Leeds 2 (August 15)

LECTURER IN MATHEMATICS; and a LECTURER IN STATISTICS at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

SCHOLAR (with an honours degree in physics or mathematics) IN THE ASTRONOMICAL SECTION of the School of Cosmic Physics at Dunsink Observatory, for research in solar spectroscopy or stellar photometry—The Senior Clerk, Dublin Institute for Advanced Studies, 64 Merrion Square, Dublin (September 1).

LECTURER (with a good honours degree in zoology and preferably some research experience, not necessarily in the tropics) IN ZOOLOGY; and a LECTURER or SENIOR LECTURER (with a degree in agriculture (or equivalent qualification) and preferably some research experience in animal husbandry) IN ANIMAL HUSBANDRY, at the Imperial College of Tropical Agriculture, Trinidad, B.W.I.—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, Strand, London, W.C.2 (September 15).

ASSISTANT EXPERIMENTAL OFFICER (with experience in laboratory work, preferably biological) IN THE PHYSIOLOGY DEPARTMENT—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire

ASSISTANT LECTURER, Grade B (honours graduate) IN PHYSICS—The Principal, Brighton Technical College, Brighton 7.

ASSISTANT PHYSICIST (Basic grade) at the Regional Radium Institute, Bradford—The Secretary, Royal Infirmary, Bradford.

DEMONSTRATORS IN (*a*) AGRICULTURAL BOTANY (preferably with an interest in plant physiology); (b) MICROBIOLOGY (with interests in dairying or soil microbiology); and (c) AGRICULTURAL CHEMISTRY (with qualifications in agricultural chemistry or chemistry)—The Registrar, The University, Nottingham.

LECTURER IN CHEMISTRY—The Secretary/Treasurer, Royal Technical College, Glasgow.

MECHANICAL and ELECTRICAL ENGINEERS (with, or obtaining, a first- or second-class honours degree or equivalent in mechanical or electrical engineering), for important projects at Ministry of Supply Establishments in the South of England, which include research and development on ram-jet engines and gas turbine propulsive systems for supersonic speed; mechanical and electrical devices for projectiles and rockets; instrumentation; aircraft and aircraft equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.436/6A.

READER IN MARINE BIOLOGY at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 31).

RESEARCH ASSISTANTS IN CHEMISTRY—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18.

SCIENTIFIC EXHIBITIONS ASSISTANT, Assistant Experimental Officer grade (with G.C.E. (advanced) in two scientific subjects or equivalent, and preferably with drawing office experience and an interest in display work), for work in the Publicity Section of the Department of Scientific and Industrial Research in London—C.M.956, London Appointments Officer, Ministry of Labour and National Service, 1–6 Tavistock Square, London, W.C.1.

SENIOR LECTURER IN PHYSIOLOGY AND PHARMACOLOGY at the Technical College, Bradford—The Director of Education, Town Hall, Bradford.

SENIOR TECHNICIAN, Grade 1 (with a wide knowledge of histological techniques), IN THE MORBID ANATOMY DEPARTMENT, to be responsible for the routine work under the direction of a Chief Technician—The Secretary, St. Albans City Hospital, Normandy Road, St. Albans, Herts.

PERMUTIT ION EXCHANGE MATERIALS

The use of Permutit Ion Exchange Materials in many roles distinct from water treatment, has resulted in the development of numerous new industrial processes giving improved results and lower running-costs. Some materials now available are :—

Zeo-Karb Na. A sulphonated coal product containing both strong and weak acid groups.

Zeo-Karb 215. A nuclear sulphonated phenol resin containing also hydroxyl groups.

Zeo-Karb 225. A unifunctional cross linked sulphonated polystyrene resin in bead form of high capacity and exceptional chemical and physical stability.

Zeo-Karb 226. A unifunctional cross linked methacrylic acid resin in bead form containing only carboxyl groups as the ion active groups.

De-Acidite E. A high capacity anion exchange material of medium basicity.

De-Acidite FF. A unifunctional very highly basic anion exchange resin in bead form based on cross linked polystyrene and containing quaternary ammonium groups.

De-Acidite G. A unifunctional weakly basic anion exchange resin in bead form based on cross linked polystyrene and containing diethylamino groups.

De-Acidite H. A material similar to "De-Acidite G" but containing dimethylamino groups.

Bio-Deminrolit. A mixed cation and anion exchange resin for demineralisation in a single column.

Decalso F. A synthetic sodium aluminium silicate suitable for the separation and concentration of vitamins and hormones.

Decolorite-Asmit. A resin of high porosity for removing colour from solutions.

Permaplex C-10. A highly selective cation exchange resin membrane containing SO_3H groups.

Permaplex A-10. A highly selective anion exchange resin membrane containing quaternary ammonium groups.

For full technical information please write to: THE PERMUTIT COMPANY LIMITED. Head Office and Laboratories: Dept. V.H.92, Permutit House, Gunnersbury Avenue, London, W.4. Telephone: CHIswick 6431

Permutit Ion Exchange Materials — Made in Britain by British Labour

LECTURES AND COURSES

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGY

POSTGRADUATE COURSE IN APPLIED GEOPHYSICS

The course is designed mainly as a basic training in methods of geophysical prospecting. It comprises lectures and practical and laboratory work with the main types of prospecting-equipment, together with a summer field course of six weeks' duration The normal entrance qualification is an honours degree in physics with some knowledge of geology, or an honours degree in geology with subsidiary physics, but graduates in other sciences who have reached a satisfactory standard in these subjects may be considered The course will commence in October, 1956, and finish the following September. Candidates will be required to submit a detailed report on their field work, and this will be combined with the results of a written examination for the award of a Master's degree. The fee for the course, including the examination fee, is £71 1s. In certain instances a maintenance allowance may be awarded

Further details may be obtained from the Registrar, the University, Edgbaston, Birmingham, 15, and applications for admission should be sent to him not later than September 1.

G. L. BARNES,
Secretary

The University,
Birmingham, 15.

NORTHERN POLYTECHNIC

HOLLOWAY, LONDON, N 7

Principal A. S. M. Symons, Ph.D., B Sc., A R.C.S., D.I.C., F Inst.P.

Day and evening courses for the internal and external B.Sc. degree examinations of the University of London in chemistry, physics, mathematics, botany, zoology and geology. Facilities for research in science (full-time and part-time). Courses for the M Sc. degree by written examination and dissertation in mathematics, physics and chemistry . Day and evening courses for the Grad R I.C and Grad.Inst P. examinations Courses are also conducted (day and evening) for the intermediate examination of the Pharmaceutical Society, intermediate B Pharm. and first medical examinations of the University of London, and for the general certificate of education. Next session begins September 24, 1956.

Prospectus on application Tel: NORth 1686

COUNTY BOROUGH OF BOURNEMOUTH

BOURNEMOUTH MUNICIPAL COLLEGE OF TECHNOLOGY AND COMMERCE

Principal: M. L. Yates, M.A (Com.), M.Sc Tech., Ph.D., M I.Mech E

Full-time and part-time courses are provided in preparation for the following: B.Sc. General (Chemistry, Physics, Biology, Mathematics); B.Sc Engineering (Electrical; Mechanical); B.Sc. Economics; University of London External Degrees; Accountancy. Provision is made for students' social and athletic interests.

Application for admission should be addressed to the Principal, from whom any further particulars required, may be obtained. Telephone Bournemouth 1520-1.

UNIVERSITY COLLEGE, LONDON (Gower Street, W C.1). Dr. D A. Denton (University of Melbourne) will give a Public Lecture entitled "Regulation of Sodium Ion Content in Sheep with Parotid Fistulae" on Tuesday, July 3 at 5 15 p m.—Admission free, without ticket. E. A L. Gueterbock, Secretary.

OFFICIAL APPOINTMENTS

ASSISTANT CONSERVATOR OF FORESTS, CLASS 1

CYPRUS

To administer the Forestry College at Prodromos and to be responsible for the teaching of its syllabus. Candidates must possess a university degree in forestry, with experience of teaching foresters. Appointment on contract for four years in the salary scale £1,236 to £1,548, plus an overseas allowance of 20 per cent of salary. A gratuity of £37 10s. is payable for each completed three months of satisfactory service. Outfit allowance of £30. Free passages for officer, wife and up to three children on appointment and satisfactory completion of contract Government quarters at moderate rental.

Apply, giving brief particulars, to the Director of Recruitment, Colonial Office, London, S.W 1, quoting BCD.61/17/07.

UNIVERSITY OF MANCHESTER

Applications are invited for posts in the Department of Physics at the following grades: Senior Lecturer, Lecturer and Assistant Lecturer. Salary scales per annum: Senior Lecturer £1,400 by £50 to £1,750; Lecturer £650 by £50 to £1,350; Assistant Lecturer £550 by £50 to £650. Initial salary and status according to qualifications and experience. Membership of F.S S.U. and children's allowance scheme.

Applications should be sent not later than July 4, 1956, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained

---

UNIVERSITY OF DURHAM

The University is about to install an electronic digital computer (Pegasus) and invites applications for the post of Director of the Computing Laboratory, which will be situated in Newcastle-upon-Tyne. The appointment will date from October 1, 1956, or such date as may be arranged The initial salary will be within the scale for Readers (£1,450 to £1,750) with family allowances and membership of F.S.S U.

Further particulars may be obtained from the undersigned, with whom twelve copies of applications, including the names of three persons to whom reference may be made, should be lodged not later than Saturday, June 30, 1956

E. M. BETTENSON,
Registrar.

University Office,
46 North Bailey, Durham.

NATIONAL VEGETABLE RESEARCH STATION

ENTOMOLOGY SECTION

SCIENTIFIC OFFICER

Applications are invited from honours graduates for ecological and population studies of soil pests as affected by insecticides. Salary for men £514 per annum, rising to £933 (£666 per annum on confirmation); salary for women lower but equal pay being introduced. Starting salary according to age, qualifications and experience. F.S S U. superannuation.

Applications (four copies), with names and addresses of three referees, to the Secretary, National Vegetable Research Station, Wellesbourne. by July 7, 1956.

EXPEDITION TO ANTARCTICA

Geologists required by Falkland Islands Dependencies Survey for service in the Antarctic for 30 months under conditions which are a test of character and resource. Commencing salary according to age in scale £400 rising to £540 a year with all found including clothing and canteen stores. Free passages Liberal leave on full salary Candidates, preferably single, should possess an honours degree in geology although those with lower qualifications may be considered. They must be of high physical standard and have a genuine interest in polar research and travel and a real enthusiasm for hard work under trying conditions.

Write to the Crown Agents, 4 Millbank, London, S W.1. State age, name in block letters, full qualifications and experience and quote M3B/43195/NF.

AUSTRALIAN NATIONAL UNIVERSITY

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

Applications are invited for the following posts in the Department of Medical Chemistry (Head of Department: Professor Adrien Albert): Two Research Fellowships (Organic Chemists); one Senior Research Fellowship; and one Research Fellowship (or two Research Fellowships). (Physical Chemists, with experience in spectroscopy and electrochemistry) The main work of the Department is on heterocyclic compounds, especially pteridines, pyrimidines and purines and on chelation of metals. Successful candidates will be expected to take up duties in Canberra in September, or soon thereafter, when the Department will be transferred from London to newly completed and well equipped laboratories Commencing salaries will be determined within the ranges £A 1,900 to £A 2,350 (Senior Research Fellowship) and £A 1,200 to £A 1,800 (Research Fellowship). Appointments will be for three years in the first instance, from date of embarkation Reasonable travel expenses will be paid and assistance will be given on housing. Superannuation is on the F.S.S.U pattern.

Further particulars should be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close on July 23, 1956

H.M. OVERSEA CIVIL SERVIC

CHEMIST, GEOLOGICAL SURVEY OF UGANDA

Qualifications. First- or good second-c honours degree in chemistry. Candidates must prepared to spend the greater part of their on analysis of ores, minerals and rocks. Pre ence will be given to candidates with experie in such work Duties. Analysis of ores, ro and minerals, with particular reference to the of tungsten, beryl, niobium and tantalums, analyses of limestones. to work in close co-op tion with the department's ore-dressing laborat Terms of appointment. On permanent and sionable or contract/gratuity terms with em ments in the scale £816 to £1,620 per ann Variable cost of living allowance. Outfit all ance. Free passages. Quarters provided rental. Generous leave. Free medical attent Income tax at local rates.

Apply to Director of Recruitment, Colo Office, London, S W.1. State age, qualificati and experience. Quote BCD.105/9/06.

COUNCIL OF SCIENTIFIC AND INDUSTRIAL RESEARCH

Applications invited for post of Direc National Metallurgical Laboratory, Jamshed Work consists mainly of fundamental and plied research in ferrous and non-ferrous me and minerals with view to develop and exp the primary and secondary metallurgical indus of the country. Applicants should possess: High academic qualifications; (ii) published search work on metallurgy and physics or phys chemistry as applied to metallurgy; and (iii) pr tical experience of modern metallurgical proces Preference given to those with at least ten ye administrative experience in an Institution of pute or large industrial concern. Salary, Rs.2, per month in scale Rs.2,000 by Rs.100 to Rs.2, (£1,800 by £90 to £2,250 per annum appr mately). Higher salary to exceptionally quali candidate. Appointment on contractual basis period of three or five years. The incumb selected eligible to join Council's contribut provident fund. Unfurnished bungalow at 10 cent of salary First class sea passage for pointee and wife.

Applications, on plain paper, giving full tails regarding age, nationality, academic qual cations, experience, etc., with copies of te monials and published papers, should reach High Commission of India, Establishment I partment, India House, Aldwych, London, W.C before July 22, 1956.

ASSISTANT CONSERVATOR OF FORESTS, CLASS 1

(FOREST RESEARCH OFFICER), CYPRUS

To administer the Research Branch of Forest Department. To continue existing resear and to initiate further sylvicultural experimen To direct entomological, pathological and clima logical research and other special investigatio To control the Library. Candidates must poss a university degree in forestry and wide expe ence of forest research. Appointment on contr for two years in salary scale £1,236 to £1, plus overseas allowance of 20 per cent of sal and cost of living allowance of 9 per cent salary. Gratuity of £37 10s is payable for ea completed three months of satisfactory servi Outfit allowance of £30. Free passages for offic wife and three children on appointment and sa factory completion of contract

Apply, giving brief particulars, to the Direc of Recruitment, Colonial Office, London, S W quoting BCD.61/17/08.

FEDERATION OF MALAYA

RESEARCH OFFICERS, MINES DEPARTMENT

Qualifications Degree in mining, metallur or chemical engineering, preferably with hono and/or postgraduate experience. Duties: R search into mining and mineral dressing pro lems and the application of results, through pi stages, to utilization in the field. The work w be carried out in the Research Laboratories of t Department of Mines and in the field. Terms appointment. On contract for three years in t first instance with emoluments in the scale £1,1 to £2,119 per annum, plus a temporary, variab cost of living allowance. Expatriation pay of b tween £91 and £133 per annum for marri officers without children and between £182 £259 per annum for those with children Gratui Free passages. Quarters provided, if available rental. Free medical attention. Generous leav Income tax at local rates.

Apply to Director of Recruitment, Coloni Office, London, S.W.1, state age, qualificatio and experience, quote BCD.99/23/01.

BIOMATHEMATICS

CEDRIC A. B. SMITH

M.A., Ph.D.

Lecturer in Statistical Genetics, University College London

The need for mathematics in biology is continually increasing. This important book is intended as a reference book for postgraduates in biology, and it also provides a readable introduction for the early stages of a biological course. The author's patient skill in exposition removes many difficulties of the more advanced processes.

"This is an excellent book ... very strongly recommended to anyone requiring either a systematic course of reading in mathematics at this (student's) level, or a reference book, and its use should by no means be restricted to those whose main interest is in biology." D. R. COX, *in* The Journal of the Royal Statistical Society.

ACADEMIC FREEDOM

N his recent book, "Academic Freedom in Our Time"* (see also p. 1190), Prof. R. M. MacIver akes a number of suggestions for the defence of ademic freedom which are intended for American aders. They require re-thinking and modification efore they could be applied in the British Commonealth; but there is much in the book that is of eneral interest and highly pertinent to issues which ave recently been raised in the Commonwealth. His atement of the intra-mural and extra-mural rights hich arise from consideration of the scholar's unction and consequent service to society have, owever, a general validity and apply in Britain and lsewhere in the Commonwealth as much as in the nited States. Three are intra-mural: the right rofessionally to decide matters calling for profesonal competence; the right to a status commenurate to his responsibility and consonant with his igh service to society and civilization; and the ght to conditions of tenure that secure him against ismissal or professional penalization save for proessional incompetence or conduct that in the udgment of his professional colleagues renders him nfit to be a faculty member. Extra-murally, there re the right to a private life free from controls that re not imposed on other citizens, and the right to xercise the same political and civil liberties that are njoyed by other citizens.

The validity of Prof. MacIver's general thesis and he application of these conditions were amply emonstrated by papers presented last August at a ymposium on the place of the Australian university n the community (see *Nature*, June 9, p. 1071), and y the difficulties in which the University of Tasmania as found itself involved in recent years, and which ave not been removed by the report of the Royal ommission of inquiry set up last year. It is abunantly clear that the main trouble and major ifficulties in Australia arise from the lack of a clear nd widespread public understanding of the nature nd purpose of a university, and perhaps especially rom the absence of any considerable nucleus among oliticians and industrialists of those who have themelves passed through a university and acquired a espect for it and understanding of the conditions ssential for its effective work. By and large, there s not that mutual understanding and respect between he university administrator and the Government, whether Minister or Civil servant, which, as American bservers have been quick to note, is one fundamental factor in the smooth functioning of the University Grants Committee in Britain.

In the symposium just noted, Prof. A. Boyce Gibson suggested that in certain respects the Australian universities stand nearer those of the United States than those of Great Britain, and for that reason alone it might well be that Prof. MacIver's book on the American universities, and also a related volume by Prof. R. Hofstadter and W. P. Metzger entitled "The Development of Academic Freedom in the United States"* (see also p. 1190), may be more effective in breaking down the parochialism which is one of the weaknesses of Australian universities, as both Prof. D. M. Myers and Prof. J. B. Polya have emphasized, than any corresponding volume from British sources. Moreover, by displaying the problem of academic freedom in its widest context, they should certainly promote the public understanding of the issues that is an essential step towards the resolution of these difficulties in Australia. Nor is Australia the only place in the British Commonwealth where excessive concern with the utilitarian or vocational aspect of a university to the neglect of its primary purpose is endangering the work of a university or the maintenance of standards.

Prof. MacIver points out specifically the danger to university work and standards inherent in any unqualified assertion that its business is to prepare the student for his place in society. In a society that practises racial segregation, for example, a university which accepts this view will tend to inculcate in the student the ideas of segregation, with the consequence that scientific knowledge regarding racial qualities would be rejected or distorted, and any university administrator or teacher who ventured to contradict the prevalent myths would be liable to be dismissed. The bearing of this observation on the situation in South Africa is obvious, and Prof. MacIver's volume should bring further support to the Universities of the Witwatersrand and of Cape Town in their stand against the policy of the Government.

It is no less relevant to the issues which have recently come to the fore at the new inter-racial University College of Rhodesia and Nyasaland. The College, which is to open its doors in March 1957—a year later than was originally hoped—will have both African and European students and, as now planned, the University College represents a compromise between the recommendations of the Carr–Saunders Commission and the original plans of the inaugural board of the Rhodesian University. Although it is a multi-racial institution, the two groups of students are to live in different hostels, but they will mix without distinction in their academic work, in sport and socially.

Concern has, however, been expressed in the House of Commons about these arrangements, the pertinent question being asked whether it was a contribution to multi-racial policy to separate the races in an educational institution like this; and on May 8 Lord Lucas asked the Government whether, in view of the Government's financial contribution to the establishment of the College, it is satisfied that the proposed residential arrangements are consistent with the principle of a multi-racial university. The Secretary of State for Commonwealth Relations, the Earl of Home, in his reply, pointed out that the Carr-Saunders Commission considered that separate hostels would be in accordance with the multi-racial principle. He believes that the University College should first concentrate on establishing conditions which will attract both Europeans and Africans to the College. When that is secured, many other developments will follow which we cannot as yet foresee.

* Academic Freedom in Our Time. By Prof. Robert M. MacIver. Pp. xiv+329. (New York: Columbia Univ. Press; London: Oxford Univ. Press, 1955.) 32s. net.

* The Development of Academic Freedom in the United States. By Prof. Richard Hofstadter and Walter P. Metzger. Pp. xvi+527. (New York: Columbia Univ. Press; London: Oxford Univ. Press, 1955.) 45s. net.

One of the most satisfactory features of the Government's reply is not the reassurance that the proposed residential arrangements are consistent with a multi-racial institution, but the clear understanding of the nature of a university institution and deep respect for its autonomy which are implicit in Lord Home's words. It was not merely that he had great confidence in Dr. Walter Adams, principal of the College, as a most enlightened and progressive man; he categorically refused to interfere from Whitehall with people who really know their business, and maintained that it is only right to leave the autonomous Council of the College to make the arrangements most likely to attract both Africans and Europeans to the College.

The question was worth asking for two reasons: as demonstrating the sensitiveness of public opinion in Britain to anything that approaches *apartheid*, and as promoting a clearer understanding of the nature of a university institution. The most disturbing feature of the whole episode is the extent to which the Labour Party, as shown by its criticism, has failed to grasp either the nature of a university or the extent to which the new University College already represents an important advance. As Sir Roy Wellensky, Deputy Prime Minister in the Central African Federation, recently observed, the fact that Africans and white people would be meeting and working at university-level is itself a great step forward. Rhodesians to-day are much more racially minded than people are in Britain, though less so than South Africans, and proposals for still closer relations might well have delayed indefinitely the establishment of the College. Account has to be taken also of the climate of opinion, and Dr. Adams was clearly right in commenting that the policy of separate residences and dining halls is not an issue of principle but a matter of practical convenience.

Dr. Adams added in his letter to Mr. Gaitskell that the Labour Party in Britain has made the task of the College Council doubly difficult by converting into a political and party issue a matter which it was proposing to solve by common sense and experience within the College community. It is fundamental to the success of the College, as he pointed out, that it should attract European students who, unlike the Africans, have the option of going to universities in South Africa. If they or their parents boycott the College, the opportunity for inter-racial co-operation within the common standards of university life would be lost.

What needs to be grasped is that segregation in living quarters is an entirely different matter if the races concerned are already close together than when, as in Rhodesia, they are far apart. In actual fact, the College will bring them a good deal close than they have ever been before, and the next step should come by growth from within rather than by pressure from without. If the autonomy of th College is respected, we may look forward to th impact on the intellectual level of Rhodesia of it academic staff. There are others on its staff beside Dr. Adams in whose integrity and judgment every confidence can be felt, and they will be helped mos in the task of rooting and spreading the academic spirit of Central Africa if they are encouraged to resist pressure from any external source. The attemp to put pressure on them can only defeat the very purpose of the College, and the lack of understanding of the issues which has been shown by political leaders in Britain is a further reason for welcoming any volumes such as those of Prof. MacIver and his colleagues referred to earlier. Such volumes can spread a clearer understanding of the nature o academic freedom, of its importance in any demo cratic society and of the ways in which it is best defended against the dangers that threaten it in ou time.

FREEDOM IN AMERICAN UNIVERSITIES

The Development of Academic Freedom in the United States

By Prof. Richard Hofstadter and Walter P. Metzger. Pp. xvi+527. (New York: Columbia University Press; London: Oxford University Press, 1955.) 45s. net.

Academic Freedom in Our Time

By Prof. Robert M. MacIver. Pp. xiv+329. (New York: Columbia University Press; London: Oxford University Press, 1955.) 32s. net.

IT is claimed in the preface to the scholarly and massive book on the development of academic freedom in the United States, which Prof. R. Hofstadter and Prof. W. P. Metzger have written under the American Academic Freedom Project, that academic freedom has become one of the central issues of our time. However, apart from Prof. Hofstadter's opening chapter on the European heritage, in which he traces the growth of the idea of toleration, and that in the second part, in which Prof. Metzger analyses with such discernment the German influence on the American universities, the book is concerned almost exclusively with the problem of academic freedom as it has presented itself in the United States from the founding of the first college to the Second World War. That is no less true of the other book, by Prof. R. M. MacIver, the director of the Project, which deals with academic freedom in our time and is also written under the auspices of the Project. Both books contribute to the clearer understanding of the issues at stake and of some of the failures that have surprised or disappointed observers outside the United States; they should help to prevent hasty judgments, as well as indicate where and how help can best be given to American universities in their defence of academic freedom, without arousing misunderstandings or making their struggle more difficult.

The book by Profs. Hofstadter and Metzger contains much that will be new to those in Britain who are interested in the question of academic freedom, and it has a wide interest in that it gives a very readable account of the development of the universities in the United States. While not purporting to present a systematic account, the book leaves the reader with a very clear understanding of the way universities have developed in the United States, of the differences in their government and organization which sometimes puzzle a British observer and of how American universities have been subjected to influences and pressures from which British universities have largely been free.

It is as a contribution to such understanding that the book is opportune. The immense range and variety of the American scene are displayed with scholarship; but detail is never allowed to become burdensome, and the primary concern with the freedom of members of a faculty is always evident. The issue of freedom for students is scarcely discussed, except where it converges on that of the freedom of the faculty. Prof. Metzger's chapter on the German influence is one of the most interesting and suggestive in the whole volume; it brings out not merely the manner whereby the conception of a university as a research institution contributed to the emergence in the United States of the modern university, in which research took a place along with teaching as a major function, the methods and concepts of science displaced the authority of religion, and in which the academic profession took on, for the first time in full measure, the character, aspirations and standards of a learned profession, but equally it makes clear the selective character of the American reaction to this German influence and especially in the matter of academic freedom. Even more than the influence of Darwinism, which itself contributed to a new conception of academic freedom, is to be noted from this chapter the vitality of the American university which constitutes one of the surest grounds for confidence that it will continue to find means to safeguard its freedom effectively, no matter from what quarter that freedom is threatened.

Prof. MacIver's book is mainly concerned with the past decade and a half and with the dangers arising from heresy hunts and the poisoning of American academic life in the name of security. His introductory chapter is a brilliant exposition of the ultimate issues involved in academic freedom both for the university and for the society of which it is a part. The ability of Americans to grasp what is at stake and to state the issues clearly has been repeatedly demonstrated by observers at the seventh Congress of Universities of the Commonwealth, in volumes such as "Government Assistance to Universities in Great Britain" and in the writings of Prof. Gellhorn, Prof. H. S. Commager and Alan Barth, as well as in earlier volumes of Prof. MacIver. Prof. MacIver's new book continues that tradition. While he describes objectively the nature of the present attack on academic freedom in the United States, the conditions and forces that constitute the real danger, his book is as valuable for the clear picture it gives of the relation between academic freedom and the ultimate function and purpose of a university—for example, its contribution to an understanding of the nature and danger of McCarthyism and the security problem in the United States. It should help to that clear understanding of the nature and function of a university which is no less essential for obtaining that support of public opinion on which it increasingly depends if its work is to be effective and the financial resources drawn increasingly from public funds are to be assured.

What Prof. MacIver brings out especially is that, in standing for academic freedom, the members of a university are doing no more than assert the essential condition under which the university is able to make its great contribution to the moral quality of society and to its spiritual as well as to its material advancement. Society as well as the university suffers if procedures are instituted which seriously affect the integrity of institutions of learning, the intellectual independence of the faculty, or the professional status of their administrators. Moreover, Prof. MacIver explains very clearly but trenchantly exactly how infringements of academic freedom are detrimental to a democratic society and why it is so important that the people as a whole should come to appreciate just what a university is and does; should learn how much of great and lasting worth it contributes to society and how essential it is that its freedom be sustained and its standards advanced; and should recognize how devoted and disinterested the work of the true scholar is.

Prof. MacIver's book is thus of interest to British readers both as a challenge to popular exposition of the meaning of a university and as a contribution to that work of assisting the community in general to regard the university not with suspicion from a distance but from near at hand with affection so that the community itself becomes the guardian of its integrity.

R. Brightman

PHYSICS OF STELLAR ATMOSPHERES

Physik der Sternatmosphären, mit besonderer Berücksichtigung der Sonne

Zweite Auflage. Von Prof. A. Unsöld. Pp. ix+866. (Berlin: Springer-Verlag, 1955.) 168 D.M.

THE first edition of Prof. A. Unsöld's book (reviewed in *Nature*, 142, 975; 1938) was a masterly achievement which presented a large field of astrophysics from a unified point of view, and for many years formed an invaluable foundation for study and research. By combining the results of physics and astrophysics, it played a particularly valuable part in developing the theory of the latter to a state where its consequences could be directly tested by observation.

The enormous advances of the past two decades have transformed the study of stellar atmospheres almost beyond recognition. Various aspects of this progress are excellently dealt with in monographs such as those by S. Chandrasekhar (1950), V. Kourganoff and I. W. Busbridge (1952), R. v. d. R. Woolley and D. W. N. Stibbs (1953), and L. H. Aller (1953 and 1954)—setting the stage for an up-to-date treatment of the field as a whole from a basically physical point of view. The new edition of Unsöld's book is therefore welcome.

The first part, on the general features of stellar atmospheres in thermal equilibrium (105 pp.), discusses the basic radiation laws, observational techniques and results regarding solar and stellar radiation, and the derivation of mean physical conditions in stellar atmospheres using the Boltzmann and Saha equations. Here there are relatively few changes.

Part 2, on the continuous spectrum and structure of a stellar atmosphere (132 pp.), has been thoroughly rewritten and more than doubled in length. The principal advances in this field have been the development of new methods of solution of the equation of transfer in grey and non-grey atmospheres, the discovery of the overwhelming contribution of the negative hydrogen ion to the continuous opacity in the atmospheres of the Sun and other stars of spectral type F and later, and the development of a more detailed understanding of the effects of convection. In addition, this section contains numerical results of calculations of continuous absorption coefficients and other quantities of great practical value in all research on stellar atmospheres.

Parts 3, 4 and 5 deal with Fraunhofer lines (293 pp.). After a detailed discussion of the practical measurement of line profiles and total intensities, the basic theory of spectral transitions is given, followed by a treatment of re-emission processes (scattering, absorption and non-coherent scattering) and the derivation of the absorption profile in the presence of damping and Doppler effects. The following chapters, on broadening by collision and Stark damping, and on the calculation and measurement of transition probabilities, represent a complete revision in structure and content; an extremely valuable new chapter gives a list of the literature on oscillator strengths up to 1954. In Part 5 (160 pp.) the physical theory is applied to the problem of line formation in an actual stellar atmosphere. After the development of the curve of growth, its application to the "Grobanalyse" determination of the mean temperature, surface gravity and composition of the Sun and of three early-type stars is described in detail. There follow discussions of "Feinanalyse" by the method of model atmospheres, and numerous other topics in the formation of stellar absorption lines are considered. No reference is made to emission lines, although it is likely that these may be formed under certain circumstances in normal stellar atmospheres, without requiring the presence of diluted radiation in extended envelopes—a subject specifically excluded by the author from his terms of reference. Part 5 concludes with a general discussion of the various systems of spectral classification.

Part 6 is devoted to solar physics (183 pp.), and begins by emphasizing the basic importance of hydrodynamics and hydromagnetics in this field. A brief summary of observational techniques is followed by an account of the solar cycle, granulation and the effect of photospheric temperature inhomogeneities on Fraunhofer lines, sunspots, faculæ and the question of a general magnetic field. A discussion of the elements of magneto-hydrodynamics precedes an account of solar and stellar flares. A further chapter deals with eclipses, the chromosphere, corona and prominences; the problem of the heating of the corona is treated in a very stimulating way, and the spectra of prominences and spectroheliogram phenomena are given a detailed interpretation.

Finally, there is an entirely new Part 7 on radio astronomy and cosmic rays (68 pp.). A historical introduction is followed by a summary of the fundamental quantities, the quiet Sun, solar bursts, radiation from the Galaxy and discrete sources, and (briefly) the 21-cm. line. The final chapter of the book deals with the problem of the relationship between radio noise and cosmic radiation.

Three appendixes give physical and astronomical constants, spectroscopic notation, and the properties of exponential integral functions. The very detailed bibliography (56 pp.) lists 1,781 references, compared with 691 in the first edition.

Prof. Unsold's gifts as an expositor of a field to which he has contributed so much are unique. The treatment of the subject is crystal clear, and the style is not only elegant and very personal, but also so lucid that even a reader with a limited knowledge of German can follow the argument without difficulty. The physically significant points are emphasized throughout, and mathematics for its own sake is avoided; close contact is maintained between theory and observation. The description is everywhere enlivened by the author's individual assessments, and his treatments of subjects on which other monographs are also available—such as solar physics—are so independent and interesting that their value is not at all diminished. On several topics, shortage of space prevents a detailed presentation of the case for certain conclusions that are perhaps controversial, and sometimes the impression is given that the subject is more 'cut and dried' than it really is.

The author's achievement in integrating into a coherent discipline a vast mass of scattered astrophysical research can scarcely be over-estimated. I venture to suggest that it would now be of the utmost value if Prof. Unsöld were to give a similar treatment (in a supplementary volume of about half the present size) of the other very closely related topics that remain, such as emission lines, shell stars, distended envelopes, novæ, variable-star atmospheres, planetary nebulæ, peculiar stars, and the interpretation of molecular spectra. Such a book, together with the present work—both written from a single point of view—would form a completed background to research on the radiation emitted from stars.

The book is very attractively produced and will be of immense value to celestial and other physicists concerned with spectroscopy, photometry, cosmic ray research and ionized gases. It places all astrophysicists incalculably in Prof. Unsöld's debt.

ARTHUR BEER

SERVICES' TEXT-BOOK OF RADIO

Electronics

By Dr. J. Thomson. Edited by the Technical Staff of *Wireless World*. (The Services' Textbook of Radio, Vol. 3.) Pp. ix+259. (London: H.M Stationery Office, 1955.) 12*s*. 6*d*. net.

THE increase in the importance and complexity of radio in the Armed Services and outside them can be measured by the changes that have taken place in Service literature on the subject. It is a far cry from the original "Admiralty Handbook of Wireless Telegraphy" to the "Services' Textbook of Radio" in seven volumes. The "Admiralty Handbook" was always good value for money to the ordinary purchaser, owing to the conditions of its publication, and this is true of the present "Services' Textbook". As stated in the foreword to the whole series, the books are intended for three distinct classes of readers—the beginner, the technician and the advanced reader. For the benefit of the beginner, more difficult sections (which do not break the continuity) are specially marked, while there are appendixes giving more advanced mathematical proofs for those able to follow them. In my opinion, this system has worked well in Vol. 3. It is a sign of the times that electrical engineers and technicians are now expected to have some knowledge of the structure of matter. The rapidity with which new materials and methods are being produced makes the acquisition of this knowledge very desirable. In this book, a very readable and accurate (to the best of my rather limited knowledge) introduction to this subject is given.

The author is, of course, an expert on valves and acquainted with recent developments. The chapters on valves are a happy blend of theory and practice, being illustrated by references to modern types, and numerical values are stressed throughout. A suggested explanation is given for the fact that oxide-coated cathodes can be used at high voltages and currents under pulsed conditions. After discussing high-frequency effects in 'conventional' valves, klystrons and magnetrons are described. Noise is given a fuller treatment than is usual in a general book of this kind. Space does not permit of more than a brief description of gas-filled devices.

This is one of the first general text-books to contain a treatment of transistors. The difficulties which beset an author writing on a subject like electronics can be seen from p. 199, where it is stated that the problems of quantity production of the germanium triode have not yet been solved'; and on p. 216 it is suggested that point-contact transistors are already in use experimentally, but the junction transistor "if it can be made in quantity, will have many important uses". I agree that there is much to be done to make cheaper and more consistent transistors in large quantities; but the above statements scarcely represent the present position. They can be understood, however, when it is observed that, although the book was published in 1955, the author's preface is dated April 1952. Interesting chapters on electron optics, cathode-ray tubes and photoelectric devices complete the book. The rationalized M.K.S. system of units is used and standard symbols, except that κ is still retained for permittivity. Needless to say, there are no 'jars'!

The book can be thoroughly recommended for any of the three classes of reader for whom it is intended. The style of writing is easy, the author seeming to be in close touch with the reader. The diagrams are clear and fulfil their purpose. C. R. Stoner

OPTICAL INVESTIGATION OF DIAMOND SURFACES

The Microstructures of Diamond Surfaces

By Prof. S. Tolansky. Pp. viii+67+143 plates. (London: N.A.G. Press, Ltd., 1955.) 40*s.* net.

INVESTIGATIONS of the surface topography of crystals have yielded many results of fundamental significance in recent years. The observations of growth spirals on the surfaces of crystals of beryl and carborundum which were made in Prof. S. Tolansky's laboratory provided some of the first evidence to support Frank's theory of the role of screw dislocations in crystal growth. Since then, it has been realized to an ever-increasing extent that the study of the microtopography of the surfaces which result from the final stages of crystal growth and from subsequent controlled sublimation, thermal etching, chemical attack or progressive dissolution provides one of the most powerful means of deriving information about the distribution of dislocations and their behaviour in crystals.

By his development and application of a series of essentially simple—yet surprisingly powerful—optical techniques which permit the quantitative study of surface features from the coarsest down almost to molecular dimensions, Prof. Tolansky has made a valuable contribution to this aspect of the physics and chemistry of solids. He has taken advantage of the opportunity provided by the publication of this volume to demonstrate the application of his methods to the study of the structures of natural surfaces, of cleavage surfaces, and of etched, polished and indented surfaces of diamond crystals. Multiple-beam interferometry, the powerful crossed-fringes technique and the light-profile method are clearly and briefly discussed and their utility and limitations outlined. The application of each technique to a number of different problems is well illustrated, and one of the most impressive features of the volume is the inclusion of one hundred and forty-three photomicrographs of outstanding quality.

The distribution of trigons on natural surfaces of diamond and the microtopography of these features as determined by the different optical methods provides one of the main topics of the book. The author expresses the very definite opinion that the trigons have their origin in phenomena which occur during the final stages of crystal growth, and that they are not to be attributed to localized attack on the surface as a result of changing physico-chemical conditions in the medium surrounding the crystals after the conclusion of crystal growth. He illustrates the experiments on controlled oxidation with molten potassium nitrate which have been carried out in his own laboratory with a further series of fine photomicrographs. No evidence has been found for the participation of screw dislocations in the processes of crystal growth and controlled oxidation in diamond.

The cleavage of diamond is of considerable interest to the physicist, the mineralogist and the lapidary, and the observation that Type 1 diamonds which absorb below 3000 A. have an imperfect cleavage compared with Type 2 diamonds, which only begin to absorb below 2000 A., is noteworthy. It is suggested that this may be correlated with the supposed greater purity of the Type 2 diamonds. In other substances, there is also often a correlation between the perfection of cleavage surfaces and the purity of the specimens.

The chapters on the formation of ring cracks on diamond surfaces by the application of a relatively lightly loaded hemispherical diamond indenter and on the comparative properties of the different crystallographic surfaces of diamond and the state of polish which can be achieved on them, although representing only an interim report on work which is still in progress, will interest engineers and metallurgists who are concerned with industrial diamond tools and indenters.

With his adequate elementary introduction to the optical techniques, and his beautiful illustrations of their application, the author can scarcely fail in his main objective in writing this book, which was to interest as wide a variety of workers as possible in the methods for the investigation of the microtopography of surfaces which have been developed in his laboratory. J. W. Mitchell

Evolution of a Scientific View of the Universe in the Physics of the Seventeenth and Eighteenth Centuries

By B. G. Kuznetsov. (In Russian.) Pp. 344. (Moscow: Academia Nauk U.S.S.R., 1955.) 12 roubles, 25 kopecks.

THIS is the first of three volumes, published in the U.S.S.R., dealing with the emergence under the impact of science of a rational attitude in interpreting the universe. The present volume covers the age of Galileo and Newton. It is the result of careful studies of original writings: scientists of all nations are considered, and the story of their life and work is told with painstaking objectivity.

Unfortunately, the book is not so much concerned with the growth of scientific as distinct from pre-scientific thought as it is concerned with the political implications of this growth. The philosophical views of scientists are given undue prominence; they are placed side by side with the views of philosophers and other non-scientific writers and given good or bad marks by the way of appropriate quotations from Marxist authorities. All this is embedded in lengthy and incoherent narratives of political events and economic developments, submerging every finer and more subtle feature of scientific thought. The author, presumably an expert in historical documentation, seems to have only second-hand knowledge of science and is given to modes of pre-scientific thinking.

Science is presented in this book as a pitifully dull assemblage of trivial facts and outmoded speculations; unfortunately, this approach is not confined to Communist countries or to writers with Communist leanings. It is repellent to most scientists, who are in any event wary of history. Soviet scientists are not likely to take a more friendly view of a book of this kind than their Western colleagues. The present work could not even be recommended as a history of the social relations of science, although this is its main subject. R. EISENSCHITZ

Rufiji

By R. de la Bere Barker. Pp. 157+13 plates. (London: Robert Hale, Ltd., 1956.) 15*s*. net.

THIS is a simple and unpretentious account of life in the wilds of East Africa, with special reference to the birds and beasts, from hyenas scavenging around the native villages to the elephants that also come occasionally as unwanted visitors.

"One day," writes the author, "while I was resting in the shade of the high bank beside a water-hole from which we had drawn water for our tea, four elephants in file came striding up a path in the dry river bed of the Matandu River. They had a mighty thirst, and those who have experienced the scorching sun of the dry season in that land can sympathize with them. The tall elephants came right up close before they saw me and then they all made the neatest right-about-turn in complete silence. Off they went, one behind the other, just as they had come, perhaps reflecting gloomily to themselves that all the best places were being spoilt by trippers these days."

The illustrations are from most excellent photographs; for example, the plate facing p. 129, which is an aerial snapshot of a packed mass of hippopotami at rest on a mud bank. Such pictures bring home to one some idea of the teeming wild life of Africa, a wild life growing rapidly less before the advance of white settlements. Mr. R. de la Bere Barker is to be envied his long years among the creatures of this Rufiji area; the fish in the river, the snakes and other reptiles, the teeming insect throng, the innumerable birds, the many mammals, including the natives, are all described with a simple vividness that brings them to life on the printed page. FRANCES PITT

Organic Chemistry

By Prof. Lewis F. Hatch. Pp. vii+324. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 34*s*.

THIS very readable text-book is written for those, such as agriculturists and nurses, to whose main studies organic chemistry is ancillary. Prof. L. F. Hatch devotes thirteen of his twenty chapters to the more formal aspects of the science. He considers the simpler classes of compounds, the preparation of some prominent ones, and the behaviour of functional groups. His descriptions are clear and thorough, and he uses up-to-date reactions. Conforming to his plan, he does not account for chemical behaviour by the electronic theory or bring in quantitative work. His later chapters deal with such subjects as detergents, dyes, elastomers, enzymes, fats, fibres, medicinals, pharmaceuticals, and proteins. Each chapter ends with students' exercises and suggestions for further reading.

As is to be expected, much emphasis is laid on the economic and industrial application of the compounds. Whether he is discoursing on aspirin, rodenticides, or on chemicals to keep bread fresh, Prof. Hatch always makes his subject one of absorbing interest. His brightly written book, with its well-selected half-tone plates, is to be recommended to the class for whom it has been written. Moreover, the up-to-date reactions and the coverage of subjects such as petroleum and agriculture make this a suitable volume for a school science library. G. FOWLES

Bibliography on Hearing

Prepared by the Psycho-Acoustic Laboratory, Harvard University. (S. S. Stevens, Director; J. G. C. Loring, Compiler; Dorothy Cohen, Technical Editor.) Pp. vi+599. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1955.) 55*s*. net.

THIS remarkable compilation of more than ten thousand titles of publications on hearing up to the year 1952 inclusive represents a second edition of an earlier less ambitious "Bibliography on Audition", which was published in mimeographed form in 1950. In the first part of the work, titles are arranged alphabetically under the name of the first author, with cross-references in the case of multiple authorship. There is also a list of anonymous publications. Unabbreviated titles are listed in their original language, and are followed, if necessary, by a translation into English. The references are given in the abbreviations laid down in the "World List of Scientific Periodicals" (Oxford, 1934).

A classification of the subject under 315 headings is appended. The usefulness of this list is naturally limited, and its accuracy rather doubtful, as, in the majority of cases, the judgment of the compiler rests on titles only.

A glossary of abbreviations used in the references and definitions of relatively unfamiliar words, mostly from the Slavic languages, form a useful addition to a book which every worker in the field of hearing is bound to welcome as a guide to an alarmingly voluminous and widely dispersed literature.

THE ATOMIC ENERGY RESEARCH ESTABLISHMENT

THE FIRST TEN YEARS

THE passing of the first ten years of the Atomic Energy Research Establishment, Harwell, was marked by a series of open days held in the last week of May. The last such occasion was in 1950, at which time the nuclear power programme was in its infancy and the work of the establishment was directed principally to helping the Industrial Group with the design problems of the production factories. As a result of the substantial relaxations in security classification made before the Geneva Conference on the Peaceful Uses of Atomic Energy last year, it was possible to show a large proportion of the work and the achievement of the Establishment in the first critical decade, much of it for the first time. Indeed, it proved possible to invite more than two thousand scientists and technologists from industry, government research establishments and universities to a 'University Open Day' on June 1, when visitors were able to move freely about the Establishment and select which of the exhibits they wished to see. Earlier in the week, members of both Houses of Parliament, correspondents of the international and technical Press and representatives of the surrounding district were invited to join parties touring the principal exhibits.

In the past five years the Atomic Energy Research Establishment has grown to be one of the largest research establishments in Great Britain. This rapid increase in size has been matched by a great increase in the available experimental facilities. New laboratories for the Chemical Engineering and Metallurgy Divisions have been built, and a new wing specially designed for the easy handling of highly active alpha-emitting materials has been added to the main radiochemical building. The Chemical Engineering Laboratory is of particular interest; it is a galleried building carefully designed for the speedy erection of large pilot-plant scale experiments involving active materials. In addition to BEPO and GLEEP, four other reactors are now in operation. All four new reactors are low-energy reactors primarily designed for research into the reactor physics of a particular system. Thus DIMPLE is a heavy-water reactor in which many different types of core can be built; for example, the basic design of the Materials Testing Reactor DIDO, now approaching completion at Harwell, was investigated in this reactor. Another reactor ZETR was built in order to determine the basic physics of simple types of low-energy homogeneous aqueous reactor. Of special interest are the reactors ZEPHYR and ZEUS, which are the low-energy precursors of the fast reactor experiment now under construction at Dounreay. It is especially interesting that, in the ZEPHYR reactor, experiments have revealed that, for each plutonium atom undergoing fission in the core, 1·7 atoms of uranium-233, another fissile nuclide, are produced in a thorium blanket by capture of neutrons escaping from the core.

In general, the work of the Establishment is now concerned with the basic science and technology of all the civilian aspects of atomic energy, although some assistance is given to the Weapons Group on specific problems. Thus for two years the Establishment carried out technology and feasibility studies on the prototype graphite-moderated gas-cooled reactors which are now being built at Calder Hall. The first reactor there became divergent just before the open days began, and the heat produced will be used for generating electricity for the National Grid in the autumn. Harwell has now a good deal of work to do in helping industry in the development and design of the improved power stations of this kind which are to be built by the Central Electricity Authority in Stage I of the government nuclear power programme. Among examples of this kind of work shown was the continued study of the reaction between carbon dioxide and graphite in a 'loop experiment' in the BEPO reactor.

Work is going on at Harwell and in the Research and Development Branch of the Authority's Industrial Group on the second stage of the nuclear power programme, when it is expected that plutonium from the Stage I reactors will be available to enrich reactor fuels. Reactors of two kinds are being considered for this stage: one uses light (that is, ordinary) water as both coolant and moderator; the other uses liquid sodium as coolant and graphite as moderator. The technical problems involved in either of these reactor systems require a good deal of development work, particularly on the acute corrosion problems which arise. Their main advantage over the gas-cooled type is that they have a lower initial uranium investment and may have slightly lower capital costs. It is expected that a prototype of the selected reactor will be built in about 1960, and, if they prove to be attractive economically, they might replace the gas-cooled stations in the later 1960's. The work shown on these competitive systems included the water and liquid sodium loops installed in BEPO.

Research and development work is also proceeding on reactors the potential large-scale use of which is still further off in time—the 1970's. The object here is to achieve 'breeding' in order to reduce the amount of uranium required to develop power by a hundredfold. The 'fast reactor' is the first of these. A large-scale fast power-reactor experiment is being built at Dounreay in the North of Scotland and two precursors, ZEPHYR and ZEUS, have been built at Harwell to study the breeding potentialities and the nuclear properties of fast reactors using plutonium and uranium-235 as fuel. ZEUS, which was on show during the open days, has the same physical size and design as the Dounreay reactor, but is operated at a very low power level in order to study the physical characteristics of the reactor system. A number of other advanced reactor systems are being studied. Among these is the homogeneous aqueous reactor which uses a liquid instead of a solid fuel; the liquid is likely to be a uranium salt in heavy water. Some of the work on the continuous processing problems involved in these reactors was shown in the Chemistry and Chemical Engineering Divisions. Work on other systems such as the liquid metal fuelled system and the high-temperature gas-cooled reactor was exemplified by current work in chemical engineering on the problems of dissolution in liquid metals, and in metallurgy on the fabrication of ceramic and cermet materials.

In order to carry out this programme, an extensive range of experimental and testing facilities is required. Typical of the extensive experimental facilities required for such a programme is the new wing which has been added to the Radiochemical Laboratory. This laboratory area is fully equipped for the handling of relatively high levels of alpha-activity. Flexibility, which is of great importance in such laboratories, is obtained by the use of free-standing glove-boxes. All the essential services are fed to these boxes from the roof void, and maintenance or replacement of components inside the boxes is performed in a specially designed area to which access may only be obtained in a protective rubber suit. The eight-year-old general-purpose BEPO reactor is currently being used for at least fifty experiments, and so several new reactors for specific purposes are being built. DIDO, models of which were on show, is a materials testing reactor which is expected to be completed in August. The neutron intensity thus made available will be forty times greater than that in BEPO, and development work will be enormously speeded up thereby. PLUTO is a similar reactor to DIDO except that there are extensive facilities for the testing of loop circuits installed in the reactor. LIDO is a swimming-pool reactor intended primarily to help solve the problems of reactor shielding design.

The isotope programme will also benefit from the increased flux available in reactors like DIDO and PLUTO. At the moment radioactive cobalt-60 is produced at the rate of about 12,000 curies per annum for hospitals and industry. It is expected that DIDO and PLUTO will produce about 50,000 curies of cobalt-60 per annum. Even then there will not be enough of this material to meet the rapidly expanding demand. In general the facilities for developing the applications of radioisotopes to industry are being expanded. An interesting feature of this expansion was the formation of the Technological Irradiation Group a short time ago, and some of the lines upon which the Group is developing were shown. An important feature of the work of this Group is the close collaboration with industry which is to be increasingly encouraged in the future. Stable isotopes are also produced in electromagnetic separators, two of which were shown by the General Physics Division. The latest of these to be developed has a specially designed high resolution for the heavier elements.

The very extensive supporting technology required for an atomic energy programme in all its stages was demonstrated by work going on in many of the laboratories. For example, it is very important to undertake a preliminary ore-separation at the mine, and the mineral-dressing laboratory at Harwell is investigating these difficult problems. The Electronics Division is concerned with the development of apparatus for radiometric geological survey to assist in uranium and thorium prospecting, and equipment for prospecting and assay was shown. New methods for the production of uranium and thorium metals from purified oxides are continuously under development, and work in this field and in the field of fabrication of prototype fuel elements for research reactors and reactor experiments was on view. The Reactor Division is primarily concerned with the setting up of experimental critical assemblies of uranium and moderators for all new-type reactors in the programme, and in this way the physics of the reactors can be studied. The chemists and chemical engineers were able to show a great deal of their work on the processing of reactor fuels and on the methods used in separation of the useful fission products and the disposal of the remainder. Among the most interesting examples of this kind of work were experiments designed to investigate the processing of reactor fuels by high-temperature melting, slagging and vaporization techniques. Such methods may in the long run eliminate the expensive dissolution and metal recovery stages necessary in wet reactor-fuel-processing methods. It is expected that large quantities of the recovered useful radioisotopes will be sold to industry in increasing amounts. There is also a considerable amount of co-operation with industry in the development of the important moderator and fuel element materials such as graphite, heavy water, zirconium and beryllium and in the development of the complex electronic instrumentation of the whole project. So far more than four hundred instruments have been developed by such collaboration.

In addition to the technological work of the Establishment, about 20 per cent of the staff work on fundamental research in nuclear physics, radiochemistry, solid-state physics and theoretical physics. The work in nuclear physics is concerned with the use and development of fundamental research tools such as the cyclotron and linear accelerators. The development work on proton linear accelerators and high-energy machines is, for example, concerned with the accelerator to be used as an injector, the magnet and radio-frequency power triode valve design. The first tank of a 50-MeV. proton linear accelerator with its auxiliary equipment has been completed. Other important work of the Establishment includes a long-term research programme on the possibility of controlled thermonuclear reactions. This programme is of great scientific interest since it combines the field of high-temperature and nuclear physics; but it is far away from any practical application.

A. H. S. MATTERSON

PROPULSION PROBLEMS IN HIGH-SPEED FLIGHT

By H. CONSTANT, C.B.E., F.R.S.

THE Parliamentary and Scientific Committee recently visited the National Gas Turbine Establishment, Pyestock, and inspected some of the research and development work proceeding there. The Committee was shown a general cross-section of the interests of the Establishment; but the greater part of the visit was devoted to work on the engine problems of high-speed flight.

The engines in production to-day, although basically designed for subsonic operation, are still quite suitable and effective at speeds up to about twice that of sound. All the old problems remain, of course, and many of these tend to get more difficult rather than easier. Thus, whatever the speed of flight, so long as we use a turbo-jet for propulsion, we shall have the aerodynamic problem of making compressor and turbine blading to give the greatest energy conversion for the lowest losses, with characteristics producing a stable and flexible engine; we shall have the problem of developing the greatest possible heat release in a combustion chamber of restricted frontal area, while maintaining a low pressure loss and a sufficient range of stable operation under all conditions of flight; and we shall have the problem of so disposing of the material with which the engine is made that every ounce of it is stressed right up to the maximum safe limit, bearing in mind all the vibratory and transient loads to which it may be subjected. We have, and always have had, these problems, to name but a few of the many which define the development background of the gas turbine. Examples of the work being done on these subjects were shown to the Committee.

Now, however, that the speed of flight is moving deeper into the supersonic range, a set of problems which are either quite new, or which have only so far given us a glimpse of their full capacity for causing trouble, are beginning to arise. Of these new problems, probably the most difficult to assess fully with our present limited experience is that of engine control. In the jet engine of to-day, the number of independent variables can be made sufficiently small to justify the practice of designing control systems by trial and error. But in an engine designed to operate over a wide range of speeds up to, say, three times the speed of sound, it will be necessary to introduce a number of new variables each of which will need controlling to suit the environment of the engine. In the first place, the swallowing capacity of the intake does not vary with aircraft speed in the same way as does that of the engine, It is, therefore, necessary to adjust the geometry of either the intake or the engine in order to match their capacity to pass air. Our present thoughts are that the intake should be adjusted as the flight speed changes, since an adjustment to the engine would be less easy to make. A similar adjustment to the capacity of the propelling nozzle to pass exhaust gases will have to be made when extra thrust is obtained by reheating, that is, by burning fuel in the exhaust pipe. This adjustment will involve the awkward process of changing the throat area of the nozzle. At high supersonic speeds it is necessary, if the highest thrusts are to be developed, to use a nozzle of a convergent–divergent shape, like an hour-glass in cross-section. If efficient and stable operation is to be obtained over a wide range of flight speeds, the outlet area of this nozzle must be made variable. This quite complex mechanism must be so designed that leakage past the movable parts is small, and cooled so as to operate satisfactorily when passing gas at a temperature of 2,000° C.

Thus a movement of the pilot's throttle, in addition to regulating the rate of admission of fuel to the main engine, and to the reheat system separately, must also control the air-intake and, in two degrees of freedom, the exhaust system as well. These controls will need to be cross-linked to a function of the aircraft speed. One of the principal difficulties anticipated here is likely to occur as a result of a sudden movement of the pilot's throttle. For if the rate of response of the engine to the various changes being made to its environment has not been correctly judged, complete loss of control may result. The Committee was given a demonstration of an engine being operated so as to give the response-rates on which a rational control system could be based.

Another difficulty that we know will become formidable at the higher flight speeds arises from the fact that the intake air will, at these speeds, be becoming uncomfortably hot. Due to the motion of the aircraft there is a rise in temperature of the air in the intake which is proportional to the square of the speed of flight. As a result of this, the temperature of the air at the engine intake increases rapidly with speed, and at 2,000 m.p.h. in the stratosphere will be as much as 350° C. After entry the air will be further compressed and would enter the combustion chamber at around 500° C. The thrust that can be obtained from an engine depends very much on how much heat can be added to the air after it has entered the combustion chamber, and this is controlled by the limits set to the temperature at exit from this chamber. At present this exit temperature is limited to about 900° C. by the materials used in the blading of the turbine. Thus the temperature rise in the combustion chamber in the example quoted above will be only 400 deg. C. This would result in a very inadequate output of thrust. The most effective way of overcoming this disability is by cooling the turbine so that the limit of gas temperature at present fixed by the properties of the material used can be raised. If, for example, the turbine can be cooled by air so that the temperature of the gases entering it can be raised from 900 to 1,200° C., then the temperature-rise in the combustion chamber would go up from 400 to 700° C. and a very considerable increase in thrust would result (about 70 per cent).

Thus, as the speed of flight increases, although the thrust requirements of the aircraft also increase, the thrust available from the engine would actually decrease if its maximum gas temperature were maintained constant. This limitation can be overcome by cooling the blades and other surfaces of the turbine so that the gas temperature can be raised without the temperature of the metal exceeding a safe limit. This process can be continued until the temperature of the cooling air, which has to be drawn from the engine, becomes so high that it can no longer act effectively. It is difficult to cool with air at 500° C. when this imparts a dull red heat to the surfaces which it scrubs ! When this limit is reached, further progress can be made by refrigerating the air before it is used for cooling; but this process involves an increase in both weight and drag. The Committee was shown a heat-transfer cascade tunnel, which has been used for providing the basic data on cooling, and a turbine designed in the light of these data, which has been operating during the past few years at temperatures as high as 1,100° C.

No very clear picture of the behaviour of a gas turbine can be obtained until its major components —its compressors, turbines and combustion chambers —have been tested separately under as wide a range of conditions as possible. From the results of such tests of components, it is possible not only to predict the performance of the complete engine but also to visualize profitable lines of development for improving the performance. Such tests as these have already become routine for engines designed for subsonic flight. They will be all the more necessary under the more arduous conditions already being experienced at high speeds. The Committee was shown tests being made for industry on compressors and combustion chambers destined for jet engines for high-speed flight, and was given demonstrations of some of the hazards involved in the testing of complete engines under simulated conditions of high-speed flight at altitude.

There is no doubt that the attainment of speeds of around 2,000 m.p.h. will pose plenty of problems for the propulsion engineer; but clear ways through these difficulties are already beginning to open up.

WHY LABORATORY ANIMALS DIE

DURING April 11–13 there were two meetings at the Royal Veterinary College, London. On the first two days the Laboratory Animals Bureau held its ninth annual congress of animal technicians ; and on the third day a symposium on infections in laboratory animals attempted to summarize current problems in this field.

The symposium was the fourth to be held, and its main audience consisted of graduates, in contrast to the congress. The fact that such meetings continue to attract attention each year is of interest in itself, indicating that the animal house is no longer considered unworthy of scientific consideration, although in many cases it still attracts too small a proportion of the laboratory budget.

To compare laboratory animals with chemical reagents is an analogy that has become hackneyed and, if followed too far, is misleading. Reagents they may be to the biologist, but they have characteristics distinguishing them sharply from the inanimate substances with which the chemist has to deal. They are not inanimate but living ; and they are not a homogeneous mass but distinct individuals, however nearly the ideal of individual similarity or uniformity may be approached.

Laboratory animals are thus exposed to one especial hazard, namely, accidental intercurrent infection. As a result of this hazard the animal may die, or the group lose any degree of uniformity it may have possessed before infection or might be expected to possess without it, and then its value as a reagent is diminished or destroyed. The deaths from intercurrent infection are not accurately known except in those laboratories where careful records are kept—and there are too many where they are not. A. A. Tuffery, speaking at the symposium on epidemiology and laboratory mice, and Dr. J. S. Paterson, in his paper on the control of infection in rabbits, both indicated that such losses are far from negligible, and may on occasion be disastrous ; nor can a remedy be proposed in the absence of more detailed recording of incidental losses and their analysis and investigation. This point is to-day widely, if not universally, appreciated, and to recognize a problem is the first stage towards its solution.

The problem is not an exclusively veterinary one. The emphasis in every paper was not so much on the treatment of infection as an untoward experience of individual animals, but on its prevention, control and elimination. Prof. W. L. Weipers, in his paper on the control of infection in laboratory cats and dogs, particularly stressed this approach, as did Dr. R. F. Gordon, speaking on the control of infection in laboratory poultry. A more particular approach was indicated by Dr. M. H. Salaman, who has examined vaccination as a method for the control of ectromelia in mouse colonies ; and by Dr. Joan Taylor, who dealt with the commonest, and therefore the most important, of all infections—*Salmonella* infection in laboratory animals. Dr. B. Moore and Dr. A. P. Goffe spoke respectively on infection in laboratory guinea pigs and infections in laboratory monkeys. Indeed, four out of eight titles included the word 'control', and all had a decidedly epidemiological twist. The same theme was emphasized by the chairman, Prof. J. W. Howie, who also added that non-bacteriologists might perhaps with advantage learn to attribute some of their losses, if recorded, to infection rather than to the natural tendency of animals to die.

That laboratory animals do die when they are required to stay alive is beyond dispute. The proportion of those born that fail to survive to weaning age may in some species, for example, rats and rabbits, be as much as one-fifth, or more. Nor are serious losses confined to the nursing period ; disease may take its toll on occasion at any age. That the wastage should be so high in rats is alarming ; yet very little was mentioned at the meeting about infection in rats, for the reason that very little appears to be known. Something is known about rabbit diseases, but not enough to prevent serious infantile losses. Mouse colonies have been the subject of many classical epidemiological experiments, and some thirty or more incidental infections of mice have been described, four of which are of outstanding importance (ectromelia or mouse pox, salmonellosis, focal necrosis of the liver or Tyzzer's disease, and infantile diarrhœa). Yet, of two out of these four the ætiology is unknown or uncertain, in one the infection is extremely widespread if not universal, and in one only is there any prospect of real control through vaccination.

The situation with regard to guinea pigs is better, for their bacterial diseases at least have been studied in some detail ; but new light has been thrown on their possible mode of transmission through the conjunctiva or, possibly, the upper respiratory tract. Nutrition and other environmental factors probably play an important part in the diseases of monkeys, which in any event are too numerous and serious for any degree of complacency. The problem of keeping a considerable number of cats in one place without the serious risk of devastating outbreaks of disease is still unsolved, although much is known about the commoner diseases of this species. Dogs present fewer such problems, perhaps because of the great competence of the veterinary profession with respect to them.

A decade ago, certainly two decades, meetings of this kind might have passed unattended and unnoticed. To-day, the Laboratory Animals Bureau does not lack encouragement to continue to make both the symposium and the congress annual events.

The attendance at the congresses numbers regularly nearly two hundred, and the high standard of contributions by technicians is maintained year after year. Of particular interest this year was the paper by Dr. J. F. D. Frazer on some aspects of the breeding of laboratory animals, in which he pointed out the effect on the natural functions of the animal, especially on breeding, of such environmental factors as light, heat, diet, cage-size and design, quality of care and much besides. He was addressing technicians, animal technicians for the most part, and he seemed to be inviting them to make their own contributions to knowledge of animal care and good husbandry.

This brings up a point of more than trivial interest. The term 'animal technician' first achieved formal status six years ago, when the Animal Technicians Association was founded. After six years it is time for it to be generally adopted and for the older terms applied to animal house staff to be dropped. The grade of animal technician is recognized by many employing authorities, such as the Medical Research Council, which have undoubtedly learned that good animal technicians mean good animal material for research and investigation. Some universities recognize the grade, but others do not; the National Health Service does not, nor is the animal technician represented on the Whitley Council. Where recognition has occurred, it has been found to pay in terms of better animals, better work and (if costs are known) less extravagance through avoidable wastage. Why, then, are some employing bodies reluctant to follow the excellent lead given by others? No animal houses in Great Britain are so bad that they could not be worse; but many are not so good that they could not be better if unskilled labour were to be gradually replaced by qualified animal technicians.

Although we may regard our standards in Britain with some satisfaction (but with no complacency), too many laboratory animals still die of infection. Some of this wastage could be prevented by more skill employed in their care and management; by the application of existing knowledge of laboratory animal diseases, and by the investigation (mainly epidemiological) of diseases still imperfectly understood.

The symposium will be fully reported in Laboratory Animals Bureau Collected Papers, Vol. 4 (obtainable from the Bureau at the Medical Research Council Laboratories, Holly Hill, London N.W.3). The Congress will be fully reported in the *Journal of the Animal Technicians Association* (obtainable from the honorary secretary of the Association, Mr. A. E. Mundy, 5 Ouse Bridge Drive, Carlton, Notts).

W. LANE-PETTER

FOOD TECHNOLOGY AND NUTRITION

THE 101st meeting of the Nutrition Society (the 46th meeting of the Scottish Group) was held in the Biochemistry Department of the University of Edinburgh on April 28, under the chairmanship of Prof. G. F. Marrian, when the subject of "The Impact of Food Technology on the Nutrition of Man and Animals" was considered. In opening the meeting, Prof. Marrian stressed the enormous importance of the topic under discussion, since so much food is processed. As one speaker pointed out, if it is accepted that food processing includes all treatment received by a foodstuff from its point of origin to the point in space and time when it is consumed, then barely 2 per cent of our food expressed in terms of calories receives no processing. Prof. Marrian also referred to the bigger and almost frightening problem of world food production, and suggested that the topics to be discussed that day warranted consideration over at least several days.

The first paper, on food processing and nutritional values for man, was by Dr. H. R. Barnell and Miss D. F. Hollingsworth, of the Ministry of Agriculture, Fisheries and Food. Miss Hollingsworth, who read the paper, pointed out that the application of heat to starch is essential for its digestion; that excessive heating of fat may cause production of acrolein; and that proteins are sensitive to the application of excessive heat and to the removal of heat. Starch, sugars and proteins in foods are not normally affected by atmospheric oxygen; but powerful oxidizing agents may have an effect. Fats may become rancid on storage, particularly in the presence of air. Rancidity may also be caused by the activity of micro-organisms. Development of oxidative rancidity is affected by temperature, light, moisture and by traces of various minerals (cobalt, copper, iron and manganese) and can be controlled by addition of antioxidants. Rancidity, besides reducing the value of fat, has adverse nutritional side-effects. Of the fat-soluble vitamins, vitamin A is relatively stable to heat if oxygen is excluded. Light also accelerates oxidation. Vitamin D is moderately stable to heat, light and oxygen. Vitamin E is fairly stable to heat but is destroyed during development of oxidative rancidity in fats. Riboflavin and nicotinic acid are more stable to heat than vitamin B_1, which is the most labile of the B complex. Riboflavin is unstable to heat and light. Vitamin C is unstable in presence of oxygen and is destroyed in sunlight.

It is possible that a combination of light, heat treatment and a radiation sterilization treatment will give eventually more attractive products than those produced by present methods. While on the whole it is true that the effects of processing on the nutrients in foods tend to give an impression of losses of nutrients whenever a food is given any form of treatment, it was emphasized by Miss Hollingsworth that the processing of foods is to a large extent a necessity to make them edible and palatable, transportable and storable. The final result is therefore greatly to increase the supply of nutrients to the world's populations.

Dr. J. M. Barnes, of the Medical Research Council's Toxicology Unit, followed next with a paper on the potential toxicity of chemicals used in food technology. He mentioned that many of the substances used as food additives possess no outstanding toxic property; others which may be used as adjuncts in processing or preservation may be toxic, but are present in the food only in very small quantities. The study of non-toxic substances resolves itself into the problem of trying to prove a negative.

Food manufacturers and allied commercial interests are so aware of the problem of toxicity that Dr. Barnes considered it unlikely that any material with demonstrable toxic properties will ever be included in food prepared in accordance with reputable trade practices. However, these may appear in food in trace quantities as the result of current practices such as compounds with well-marked toxic properties and active as insecticides, fungicides, germicides or endowed with other special properties. A safe dose is one which the body can dispose of without harm to its normal metabolism. Difficulties arise when no clear-cut toxic response occurs with larger doses. There are some who suggest that in some unspecified way the prolonged consumption of such substances over long periods may injure health. It has been shown that, in the case of certain toxic substances, the disposal of small non-toxic doses may be quite different from that used when larger quantities are given.

Dr. Barnes illustrated the biological complexities by reference to maleic hydrazide, a potato sprout depressant which produces inhibition of plant growth at concentrations of a few parts per million, and yet rats and other animals will grow and thrive on a diet containing as much as 1 per cent of it. When used properly, residues of 10–15 p.p.m. may remain in the potatoes at the time they are consumed. It has been suggested by the work of Waggoner and Dimond that maleic hydrazide exerts its effects on plants by stimulating the enzymic hydrolysis of indole acetic acid, so depriving the plant of this auxin. But cytological changes include chromosome splitting. As many carcinogenic substances have a similar effect on mammalian cells, it has been suggested that maleic hydrazide should be tested for its carcinogenic effects before being used for human consumption. The uniformly negative result of tests on mammals suggests that maleic hydrazide on potatoes in 10–15 p.p.m. would not be harmful, though it does not amount to *proof* that it would be entirely safe. The steam volatility of another sprout depressant, tetrachloronitrobenzene, during cooking indicates that the physical and chemical properties of substances added to food play as important a part as the biological properties in determining whether a health hazard will be associated with their use.

While there are comparatively simple acute tests which seem adequate for distinguishing powerful carcinogens, a definition of a 'weak carcinogen' has not been provided. Surface-active agents may have interesting biological effects; but whether or not these effects will be shown if the emulsifiers are added to bread has not yet been determined.

Not only may the chemicals added to food become altered, but so too may the food itself and the products of such reactions might be toxic. The classical example is the agene process of improving flour. Agenized flour is toxic to dogs, cats, rabbits and ferrets, but rats and monkeys are relatively insensitive. Dr. Barnes quoted experiments in the United States on nineteen humans, including five epileptics, who were given flour treated with 20–30 times the usual quantity of agene but without showing any change in behaviour, general physiology or electro-encephalogram. The monkey requires at least a hundred times the dose of the active toxic agent, methionine sulphoximine, needed to induce fits in the dog. A man eating 2.000 Cal. per day as agene-treated flour ingests a dose of 1 mgm./kgm. methionine sulphoximine; the sensitive dog requires a dose of 2–4 mgm./kgm. to produce fits and kill the animal. The nature of the toxic action of methionine sulphoximine has not been defined: species differences may be due to speed and ability to dispose of the toxic substance.

Where no positive effects can be observed on animals with a given substance, then a hypothetical risk may be incurred if such a chemical is added to food. In Dr. Barnes's view, this should in some way be balanced by the simultaneous conferment of some benefit to those who incur this risk.

Mr. N. W. Pirie, of the Rothamsted Experimental Station, in his paper on unexploited technological possibilities, pointed out that the three outstanding possibilities for increased food are: the synthesis of food, the more economical use of crops of the type we already grow, and the exploitation of new primary sources of food. In his opinion we would continue to rely mainly on photosynthesis rather than on synthesis of the bulk foods. Few people get less than half their energy from vegetable sources, and most of the world's population gets nearly all its energy in this way. One solution of the food problem would therefore be to increase the amount grown.

Diets eaten in many parts of the world are inadequate, having many faults; protein deficiency being a common one. Some legume seeds contain adequate amounts of protein; but many tubers such as cassava contain very little. Many leaves, which can now be stored by refrigeration, contain as much nitrogen as the legume seeds. Investigation of systems of husbandry that would ensure large yields of protein-rich and fibre-poor leaves is a technological possibility that deserves fuller exploitation. Even normally despised grasses would be useful if grown regularly with 25–30 per cent of protein.

The protein in the leaf is already there and valuable, needing only separation from dilute carbohydrate. Since the time of Rouelle (1773) it has been extracted from leaves and coagulated. The pulper described by Mr. Pirie is the end-product of much experiment, and is reasonably satisfactory in separating juice from fibre. The protein can be precipitated from the juice by letting it age, by heating to 75° C., by adjusting *p*H to about 4 or by shaking it with a variety of water-immiscible liquids. Different preparations vary somewhat in digestibility, and the reasons for this are being investigated. Mr. Pirie thinks it wise to postpone careful feeding-trials until this phenomenon is more fully understood; but he stresses the need for a much more adequate scale of research in this important field. He considers it illusory to believe that algae, such as *Chlorella*, are peculiarly efficient at trapping light and giving a greater return per acre-year than other crops.

The sea is an under-exploited environment, and both the harvesting of marine microflora and the use of the material harvested are ripe for technological investigation. Mr. Pirie believes that, if Britain cannot continue to buy its food from the rest of the world, it must come to live on its own acres and then it must change its style of eating.

In his account of some technological developments of importance in animal nutrition, Dr. J. Duckworth first pointed out that most of the common energy sources are often too low in protein for productive purposes and must be supplemented to secure appropriate ratios of metabolizable energy to digestible protein. All protein-rich supplements are expensive, relative to the basic energy sources, and thus minimum feeding costs are realized only when supplements are added at the level that justifies the animal's needs. In practice, a margin of safety must be added, and the greater the uncertainty about the dietary protein the greater this margin must be. Sources of uncertainty are: variation in protein content among different batches of individual feeding-stuffs, variation in amino-acid composition within the total protein content, natural variation in protein digestibility, and variable effects of processing on protein quality, defined in terms of digestibility and of metabolic availability of certain important amino-acids of the digested protein. An independent source of uncertainty is variation in the metabolizable energy of feeding-stuffs disturbing the nutritive ratio.

Important features of research and technical development are studies on processing to obtain by-products of uniformly high protein value, of the inheritance of desirable amino-acid levels in feed proteins, of the synthetic production of amino-acids and of applying nitrogenous fertilizers to raise the protein content of crops of high-energy content.

In Britain there is the problem of making efficient rations for the livestock with feeding-stuffs of diverse and fluctuating origin and kind. The nation is dependent on the technological capacity of manufacturers abroad; for example, half the national supply of protein concentrates was imported in 1953 and 1954. In 1955 there was a large increase in supplies, mainly of imported oilseed meals. So far, continued Dr. Duckworth, little research on the nutritive value and still less on local processing methods has been published from most sources of these feeding-stuffs. Processing has generally a profound effect on the nutritive value of protein concentrates and, if inadequately controlled, yields highly variable products. Only on fish, herring, soya-bean and cotton-seed meals has extensive research been done, and then almost entirely from the point of view of suiting the products to non-ruminant needs. A recent trend has been to process oil-seed meals for high solubility of protein. Such materials are contra-indicated for ruminants under preferred British feeding systems. Attention is now being given to developing rapid laboratory tests of protein quality. If success is attained, an appropriate amendment of the Fertilizer and Feeding Stuffs Act would give protection against low-value protein concentrates of domestic or imported origin, and thus lead to more efficient compounding of rations.

Many members and visitors took part in the discussion which followed.

SCIENCE HOUSE, PAKISTAN

The visitor to Pakistan cannot fail to be impressed by the rapid scientific development which is taking place there. The science departments in the older universities are expanding; new universities have been created in Sind, Karachi, Peshawar and Rajshahi; the Central and three Regional Laboratories of the Pakistan Council of Scientific and Industrial Research have been established, and important research institutions, such as the Cotton Research Institute, the Jute Research Laboratory, the Pakistan Standards Laboratory and others, have come into being during the past three years. The new buildings, many of which have been completed, are very impressive. The sites are spacious and convenient, and the buildings, of pleasing design, have been planned with imagination and foresight. There is ample accommodation for many years to come, and expansion will not be hampered by considerations of space. These institutions have been provided by the State, and are a reflexion of the importance attached by the Government to the part which science must play in the development of the country.

The Pakistan Association for the Advancement of Science was founded in 1947, and has been very active, having started the publication of Pakistan's first scientific journals—the *Pakistan Journal of Science* and the *Pakistan Journal of Scientific Research*—and organized the annual All-Pakistan Science Conferences.

A new development of great importance has just been launched. The foundation stone of the Ismail Aiwan-i-Science (Science House), Lahore, was laid on January 27, 1956, jointly by Mr. Nasser Ahmad Shaikh, and the representatives of science associations from Australia, China, India, Pakistan, the U.S.S.R., the United Kingdom and the United States.

Science House will be the integrating centre for science in Pakistan. It will contain a large science library and a bibliographic, translation and documentation centre equipped for microfilming and duplication. There will be an auditorium to seat a thousand persons. There will be accommodation for a Human Relations Research Centre, which will be concerned chiefly with social science research. Science House will also contain office accommodation for the various scientific societies, together with seminar and committee rooms, and a press and publications section for the various scientific societies and organizations. There will be residential accommodation for visiting scientists, club rooms and a cafeteria.

The building is situated in the new modern residential centre of Lahore, adjacent to the new Regional Laboratories of the Council of Scientific and Industrial Research, and close to a number of important educational institutions and the proposed new site for the University of the Panjab.

This magnificent project was conceived by Dr. Bashir Ahmad and his colleagues, and has been made possible through the generosity of Mr. Nasser Ahmad Shaikh, a leading industrialist in Pakistan, who has provided the funds for building Science House.

The new building will be completed early in 1957, and the next annual meeting of the Pakistan Association for the Advancement of Science will be held in it.

George Allen

OBITUARIES

Dr. Walter Sydney Adams, For.Mem.R.S.

Walter Sydney Adams, the son of a missionary, was born in Antioch in northern Syria on December 20, 1876. He was educated at Dartmouth College and the Universities of Chicago and Munich, and was appointed an assistant at the Yerkes Observatory under Hale in 1901. In 1904 he was one of the small staff which went with Hale to Mount Wilson to start the new Observatory in California. As assistant astronomer, as assistant director, as acting director during Hale's illness, and from 1923 onwards as director, he devoted his life to the Observatory until his retirement in 1946. As a research associate of the Carnegie Institution of Washington and of the California Institute of Technology, he continued working on astrophysical problems, his last paper on the shell star α Orionis appearing in the March issue of the *Astrophysical Journal* this year. He died on May 11, 1956.

Adams's earliest publications were on line-of-sight velocities of stars, on spectroscopic binary orbits, on stars of variable velocity and on details of spectrographs and allied instruments in use in the Observatory. He showed an early interest in the spectra of novæ, in the characteristics of sunspot spectra and in the comparison of centre and limb spectra in the Sun. His measurement of solar rotation at different levels in the solar atmosphere showed that the higher strata rotate faster and with a smaller equatorial acceleration than the lower strata. His next major contribution to astrophysics, the one for which the Gold Medal of the Royal Astronomical Society was in large part awarded in 1917, was the spectroscopic determination of stellar parallaxes. The first paper with Kohlschütter on the criteria provided by varying relative strengths of spectral lines for determination of absolute magnitudes of stars appeared in 1914. Afterwards Adams extended the work to cover a much wider range of spectral types and he published spectroscopic parallaxes of thousands of stars. His work led to a direct probing of the galaxy to far greater distances than had hitherto been possible except by statistical methods.

Among much other work of his mention must be made of his analysis of high-dispersion spectra and the calibration of Rowland's scale of intensities; in novæ he noted the simple 1 : 2 : 3 relations between the velocity displacements of successive outbursts: high-dispersion spectra enabled him to detect as many as five clouds of interstellar gas in the same direction in space moving with different line-of-sight velocities. Adams also both detected the white dwarf nature of the companion to Sirius and afterwards the relativity displacement to the red of the lines in its spectrum—a displacement of +19 km./sec. as compared with Eddington's predicted value of +20 km./sec. at λ4500.

Adams was president of the Astronomical Society of the Pacific and later of the Astronomical Society of America. He was vice-president of the International Astronomical Union during 1935–49, keeping the Union alive during the Second World War. He was the senior associate of the Royal Astronomical Society, a foreign member of the Royal Society and a corresponding member of many other national academies. He was awarded the Draper Medal and the Bruce Medal in America, the Prix Janssen and the Janssen Medal in France as well as the Gold Medal of the Royal Astronomical Society. In his death the astronomical world has lost a much loved and widely revered leader. F. J. M. Stratton

Mr. P. W. Wood

It would seem strange to anyone in Cambridge to speak of Philip Worsley Wood in any other way than as "P. W.". His passing is a great loss to Cambridge and especially to Emmanuel College, as was that of his namesake Alex. a few years ago. Born in April 1880, he matriculated and entered Emmanuel in 1899.

To one who was his exact contemporary, the passing of "P. W." comes as a reminder that the ranks of those who took the Mathematical Tripos Part I in the days when there was an order of merit are becoming very thin. In 1902 he was Third Wrangler, bracketed with H. A. Webb. In 1903 he was placed in Class I, Division 2 in Part II of the Tripos, and in the next year was awarded a Smith's Prize.

"P. W." had in a high degree that facility in the solution of ingenious problems which counted for so much in the Tripos of that day. But it was not the kind of outlook for which the times were asking. With the passing of the old Tripos, mathematical fashion was for connected theory, ever widening in scope and in new points of view. Thus Wood became one of that band of teachers who held the fort for that wide range of students for whom mathematical research lay beyond their reach. As such he was an outstanding member of his College and of the Faculty. To his pupils he was devoted, meticulous and challenging. Though he retired at the age of sixty-five under the age limit, he went on teaching for the love of it until the day when he was overtaken by the illness which led to his death ten days later.

Being what he was, his original work was limited. The best known was his Cambridge Tract on "The Twisted Cubic". Not so well known was a series of papers in the London Mathematical Society *Proceedings* on algebraic invariants.

His activities turned early to College administration. A Fellow of Emmanuel for fifty-one years, he served for thirty-five years as lecturer in mathematics, for twenty-six years as librarian and for seventeen years as senior tutor, besides acting for some periods as vice-master. In University affairs he was not so prominent, though he was a junior proctor in 1917–18 and was for many years a much-valued member of the Local Examinations Syndicate.

As a man, "P. W." cannot be put into any class. He was just himself—kind and appreciative but caustic and terse in conversation, diligent in all that he undertook, working hard for little reward. Having no ambition but to serve well, he lived to serve.

Some would say that his hobbies were lawn-tennis and gardening. But truly his College was his hobby and his absorbing pursuit. His home and garden were places of renewal in the companionship of his wife, his two sons and his daughter. Is it possible that he shared with them, as he did with me, in the year 1944, the discovery that that number is just $3^5 \times 2^3$? Ebenezer Cunningham

Dr. M. A. Whiteley, O.B.E.

Martha Annie Whiteley was born on November 11, 1866, and received her early scientific training at Royal Holloway College, London, where she graduated in 1890. During the following twelve years she held appointments as science mistress at Wimbledon High School, lecturer in science at St. Gabriel's College, Camberwell, and lecturer in physical chemistry at Royal Holloway College. During the last few years of this period, from 1898, she also carried out part-time research at the Royal College of Science, and in 1902 she obtained the D.Sc. degree of the University of London (her examiners at the oral examination being Ramsay and Frankland), and in 1903 the diploma of associateship of the Royal College of Science. In the following year Tilden appointed her to be a teaching scholar on the staff of the Royal College of Science, and she was promoted assistant in 1905, demonstrator in 1908 (by which time the College had become part of the newly constituted Imperial College of Science and Technology), lecturer in 1914, and assistant professor of organic chemistry in 1920.

Her first paper, in 1900, on "The Oxime of Mesoxamide", set the pattern of her research activities on derivatives of malonic acid and barbituric acid. During the First World War, her specialized knowledge in this field enabled her to play an important part in the development of methods for the synthesis of urgently needed drugs, and she also carried out investigations on lachrymatory war gases ; for these services she was made O.B.E. She will, however, be particularly remembered for her teaching, which she greatly enjoyed. At the time of her retirement from Imperial College in 1934 she said, "When I first came to the College in 1898 I little thought to find my life's work here as a member of the teaching staff, but my love for teaching has made it seem all too short. No one who has not passed through an experience such as mine can understand the fascination which is involved in the constantly changing types of students and the human interest attaching to them". She took a particular interest in the women students, and was largely responsible for the foundation, in 1912, of the Imperial College Women's Association, of which she was president for many years. Earlier (1904–8) she had taken a leading part in efforts, unsuccessful at the time, to secure the admission of women to fellowship of the Chemical Society ; it was highly appropriate that in due course she should become the first woman to be elected to its Council (1928–31).

During the many years she spent at Imperial College, Dr. Whiteley formed a connexion with "Thorpe's Dictionary of Applied Chemistry" which in later years was to become a source of great happiness to her. She had been associated with Sir Edward Thorpe and with Sir Jocelyn Thorpe in the production of the second and third editions, and after her retirement in 1934 she continued to work on supplementary volumes and on the preparation of the fourth edition, the first volume of which appeared in 1937. After the death of Sir Jocelyn in 1940, she became editor-in-chief, and despite inevitable war-time restrictions and personal difficulties, which included the destruction of her home in an air-raid, the work went on. In the years since the War, her physical health deteriorated, but her mind remained as clear and alert as of old, and with her indomitable will she continued to edit scripts and to read every word of galley and page-proof ; it was rarely that an error escaped her. Volume XI, which, apart from a general index, was the last of the fourth edition, appeared in 1954, and the completion of this considerable undertaking gave her much satisfaction, inevitably tinged with some sadness. Her health now became progressively worse, and she died on May 24, 1956, in her ninetieth year.

Martha Whiteley's concepts of duty and service, and her way of life, were sustained by her Christian beliefs ; her memorial is in the respect and affection which she engendered in generations of students, colleagues and friends. L. N. Owen

NEWS and VIEWS

Royal Meteorological Society : Napier Shaw Memorial Prize

At the meeting of the Royal Meteorological Society on June 20 the president, Dr. R. C. Sutcliffe, announced that the first award of the Napier Shaw Memorial Prize of the Royal Meteorological Office had been made to Dr. Norman A. Phillips, of the Institute for Advanced Study, Princeton, for his paper, "The General Circulation of the Atmosphere : a Numerical Experiment", which was published in the April issue of the Society's *Quarterly Journal*. This Prize has been established as a result of an appeal to the members of the Royal Meteorological Society and to scientific instrument manufacturers for a memorial fund to commemorate the unique position achieved in meteorology by Sir Napier Shaw, the centenary of whose birth fell on March 4, 1954. It was decided to use this fund for the regular award by competition every two or three years of a Napier Shaw Memorial Prize of £100 for original essays on meteorological topics. The first competition was announced in 1954, the topic selected being "The Energetics of the General Circulation", and entries were open to anyone without restriction of nationality.

Chemistry at Hull : Prof. N. B. Chapman

With the appointment of Prof. Brynmor Jones to the vice-chancellorship of the University of Hull (see *Nature* of January 21, p. 116), the G. F. Grant chair of chemistry at Hull which he has vacated has been filled by Dr. Norman B. Chapman, reader in chemistry in the University of Southampton. Dr. Chapman was educated at the Holgate Grammar School, Barnsley, and Magdalene College, Cambridge, where he was successively scholar, research student and bye-Fellow, being University demonstrator during 1945–46. While at Cambridge he carried out research on oxidation by peroxidase systems, and on chemical warfare and anti-malarial agents. Early in 1947 he went to Southampton, becoming successively lecturer in organic chemistry, senior lecturer and, in 1955, reader. In Southampton he has built up a strong school of research with two principal lines of work : a study of the kinetics of many organic reactions, including the substitution of halogens in aromatic and heterocyclic ring systems ; and the synthesis of nitrogen-substituted halogeno-ethylamines, histamine derivatives, and other substances of potential pharmacological importance. He has a wide knowledge of physical as well as of organic chemistry, and among many other interests are cricket, rugby football and opera. The warmest wishes of his many friends at Southampton and elsewhere go with him and his wife to Hull.

Chief Colourist of the Dyestuffs Division, Imperial Chemical Industries, Ltd. : Dr. T. Vickerstaff

Dr. T. Vickerstaff has been appointed chief colourist of the Dyestuffs Division of Imperial Chemical Industries, Ltd., in succession to Mr. G. O. Mitchell, who has retired after thirty-seven years of service with the company. After leaving the University of Manchester, Dr. Vickerstaff joined Imperial Chemical Industries, Ltd., in 1935, and was at first engaged in work on problems of dyeing wool, which was carried out in the University of Leeds. This was followed by a short period at the Huddersfield Works of the Dyestuffs Division, and then in 1937 he was transferred to the Dyehouse Department at Hexagon House, which is the administrative headquarters of the Division in Blackley, Manchester. He became closely associated with the work of the newly formed Dyeing Research Section of the Dyehouse Department and was appointed head of the Section in 1942. During this period he made valuable contributions to the study of colorimetry and became a leading member of the Colour Group of the Physical Society. Overlapping with his work on colorimetry he has made a number of fundamental studies of the physical chemistry of dyeing. His text-book, "The Physical Chemistry of Dyeing", is now in its second edition, and moves are afoot to translate it into German and Japanese. In 1942 Dr. Vickerstaff was awarded the Research Medal of the Society of Dyers and Colourists as senior author of the paper "The Dyeing of Acetate Rayon with Dispersed Dyes". He was appointed an assistant chief colourist of the Dyestuffs Division in 1949.

Colleges of Advanced Technology

An extensive building programme, to start next year, in connexion with technical studies in the universities, estimated to cost about £4,500,000, was announced during a debate on technical education by Mr. R. A. Butler, Lord Privy Seal, in the House of Commons on June 21. The new buildings are to be dedicated not only to engineering and branches of technology, but also to basic sciences, especially physics and chemistry. The sum announced represents only the contribution of the Exchequer, and does not include other sums which might be contributed by industry or by the universities themselves. These colleges are in future to be designated colleges of advanced technology, and conditions for such designation were circulated on June 21 by Sir David Eccles, Minister of Education, to local authorities. The circular outlines the present organization of technical colleges, and suggests how each kind of college can best contribute to the Government's five-year plan for technical education. Regional co-ordination is essential to the success of this policy, and the Minister asks the local education authorities to co-operate fully with one another. He considers it important that the smaller technical colleges should develop as speedily as possible into colleges of technology.

In the House of Commons on June 21, the Minister named those colleges which will be recognized as advanced colleges of technology. They are: Birmingham College of Technology, Bradford Technical College, Cardiff College of Technology and Commerce, Loughborough College of Technology, The Royal Technical College, Salford, The Battersea Polytechnic, London, The Chelsea Polytechnic, London, The Northampton Polytechnic, London. Some of these colleges do not fulfil the necessary conditions at present, but it is hoped that they will do so in the near future. Among the conditions for designation as a college of advanced technology are strong direct representation of industry, besides representatives of local education authorities, universities and professional technological interests. Teaching conditions must approximate to those of equivalent standard at universities, and the staff must have opportunities for research and consulting work. The Minister lays considerable stress on the provision of residential accommodation. The circular which the Minister has sent to local authorities also describes the three kinds of existing technological colleges, referring to them as local, area and regional colleges.

Frederick D. Edwards Trust for Financial Help for Technical Students

Mr. F. D. Edwards, founder and managing director of Edwards High Vacuum, Ltd., has recently formed the Frederick D. Edwards Scholarship Trust, the purpose of which is to give financial aid to technical students pursuing or intending to pursue a course of training in science and technology. The capital of the Trust is £12,000, and Mr. Edwards has stipulated that the whole of this and its associated income must be spent within ten years. Otherwise, the trustees have a completely free hand to dispose of the money as scholarships, bursaries, prizes, small-scale grants, or in any other way they think fit. Although three institutions are specifically mentioned in the Trust deed—the Northampton Polytechnic, the National College of Instrument Technology and the Crawley Technical College—a student at any institution "giving training courses or facilities for research in any branch of science or technology" is eligible. Inquiries about the Trust and applications for grants should be made through college principals to either of the two trustees: Mr. F. S. B. Murrells (director and secretary of Edwards High Vacuum, Ltd.), at Tresco, Nevill Court, Tunbridge Wells, Kent; and Mr. A. J. Philpot (retiring director of the British Scientific Instrument Research Association), at Cranley, Bressey Grove, London, E.18.

Rain-making in Tanganyika

In a written answer in the House of Commons on May 31, Mr. Lennox-Boyd, Secretary of State for the Colonies, said that because of partial failure of the seasonal rains, the level of the reservoir at the Kazima Dam, which provides Tabora, the railway junction and administrative centre in the Western Province of Tanganyika, was dangerously low at the end of March. A new 'cloud-seeding' technique, involving the use of 2-in. naval rockets, modified to incorporate particles of sea salt, which had been evolved by the East African Meteorological Department in conjunction with the Admiralty and the Ministry of Supply, was accordingly tried out, and thirty-seven such rockets were fired between April 12 and May 2. Under the conditions prevailing, the best results were obtained when the rockets burst at about 3,000 ft., and 1·5 miles downwind of the catchment area of the Kazima Dam. The results are still being studied, but there was definite evidence that under suitable conditions cloud-seeding produces rain. A significant feature of the experiments was the repeated occurrence of rain over the catchment area some 12 minutes after seeding, and at the end of the experiments the level of the reservoir had risen by 2·5 inches, despite a daily consumption of 250,000 gallons and a high loss through evaporation. Rainfall in the catchment area during April was about one to one and a half inches higher than that measured at stations near but outside the catchment area.

The Houldsworth School of Applied Science, Leeds

The Council of the University of Leeds has approved a re-organization of the Department of Coal Gas and Fuel Industries with Metallurgy and Chemical Engineering. Under this re-organization the present Department will be replaced by a School, to be called "The Houldsworth School of Applied Science". Sir Hubert Houldsworth, the late pro-chancellor of the University, had been for some years a member of the staff of this Department, and through his work as fuel controller and with the National Coal Board was very familiar with its activities. The Houldsworth School of Applied Science will be constituted of three Departments: Gas Engineering and General Fuel Science with Ceramics, directed by the Livesey professor, Prof.

A. L. Roberts; Chemical Engineering, directed by the Brotherton professor—a newly established chair; Metallurgy, directed by the reader in metallurgy, Dr. N. J. Petch.

The European Coal and Steel Community

The Broadsheet issued by Political and Economic Planning on the "European Coal and Steel Community" (No. 389. November 21, 1955) is of some current interest in view of the possibility that institutions which have served the Community well so far may be taken as a model for the development of the peaceful uses of atomic energy. The Treaty establishing the Community was signed on April 18, 1951, and the Broadsheet briefly describes the evolution of what is the only truly supra-national organization in Western Europe which seeks to unify markets and control basic resources by eliminating six obstacles: customs duties and quantitative restrictions on coal and steel movements between the member countries; discriminatory transport rates; price discrimination for domestic and export sales within the Community area; cartels and agreements on restraint of trade; government subsidies; and government control of prices. The organization for achieving these objectives consists of an executive body, the High Authority, to establish and maintain the common market and answerable to the Common Assembly, a Consultative Committee, a Council of Ministers and a Court of Justice. The development of the Community has already passed through what may be called the opinion-forming stage and has now entered a second phase of long-term policies, European rather than national in character. As an economic experiment, the Community has been a success so far as the six countries are concerned, and Britain set up in July 1952 a joint committee for the exchange of full information of common interest and has maintained cordial relations with the High Authority ever since. What happens next in the Community depends on political rather than economic policies, and the Broadsheet points out that the view is widely held that progress is most likely in the integration of the production of atomic energy but that rejection of the European Defence Community has left it high and dry as the sole trophy of the federalist movement.

U.S. National Science Foundation: Senior Postdoctoral Fellowships

Applications are invited for the second group of senior postdoctoral fellowships to be awarded by the U.S. National Science Foundation during the current calendar year. These will be awarded in mathematical, physical, medical, biological, engineering and other sciences, including anthropology, psychology (other than clinical), geography, certain interdisciplinary fields, and areas of convergence between the natural and social sciences. To be eligible for these awards, candidates must be citizens of the United States. Annual stipends of 2,000–10,000 dollars, adjusted to match as closely as feasible the regular salaries of the award recipients, may be applied toward study or research in an accredited non-profit institution of higher learning in the United States or abroad. A limited allowance to aid in defraying costs of travel for a Fellow and his dependants will also be available. Further details can be obtained from the Division of Scientific Personnel and Education, National Science Foundation, Washington 25, D.C.

Review of Czekoslovak Medicine

The quarterly journal *Review of Czekoslovak Medicine* (1, No. 1; 1955. Praha: Státní Zdravotnické Nakladatelství (Sokolská tr. 31)), which is printed in English only, fulfils, to quote the words of its introductory article by B. Špaček, vice-chairman of the Scientific Council of the Czechoslovak Ministry of Health, "a natural and earnest desire of all Czekoslovak medical scientists to bring their work before a truly international audience. Czekoslovak physicians have regretted that, no matter how significant or valuable their work it has for the most part, because of language difficulties, been insufficiently known in foreign countries . . ." and "too often . . . the priority of outstanding work by Czekoslovak investigators" has been "denied, incorrectly, by scientists of other nations. . . ." This introductory article then mentions Czech investigators whose work is insufficiently known outside their own country and explains that "Czekoslovak science passed through its most arduous trials during the Hitler occupation", when its universities were closed and its workers were persecuted. "Only with the establishment of our People's Democracy, which is building socialism on a scientific basis, is a foresighted policy being pursued . . ." and "publishing facilities . . . have been enlarged . . ." until nowadays "fifty medical and health journals are published". The article concludes with an appeal for a friendly reception of this new journal, which is "an expression of our deep conviction that mutual understanding can bring about both lasting peace between the nations and the prosperity of all mankind".

The rest of the first issue of the journal contains scientific contributions, with annotations, abstracts and reviews. The leading article, by F. Burian, describes the development of plastic surgery in Czechoslovakia. Other contributions are: research on the pathophysiology and some symptoms of hysteria (J. Černáček); sodium citrate—one of the main causes of cardiac overloading and failure in rapid blood transfusion (P. Firt and L. Hejhal), and ascorbigen—the bound form of ascorbic acid (Z. Procházka). An annotation by K. Hubschmann deals with the venereal disease campaign in Czechoslovakia, and another, by F. Démant and T. Prehop, with acute infectious hepatitis. A note by the editor points out that references appended to the individual papers quote only the work of Soviet, Czech or Slovak authors, this being an effort to economize space and to acquaint English-speaking readers with work "less easily accessible to them"; but if it "should prove desirable to quote fully all work cited", an effort will be made to do this in future issues. The subtitle of the journal is "Journal of the Czekoslovak J. E. Purkyně Medical Association" and this commemorates one of the world's very great histologists and physiologists.

British Hat and Allied Feltmakers Research Association: Report for 1955

The eighth annual report of the Director of Research of the British Hat and Allied Feltmakers Research Association, covering the year ended August 1955 (pp. 23; from the Association, Manchester, 1955), notes that, besides continuing work on the technology of carrotting of fur, a better picture of the initial reactions in the carrotting process appears to be obtained by studying the absorption of mercury from solutions of mercuric sulphate in sulphuric acid by animal and man-made protein fibres, as there is no incipient decomposition, such as occurs with nitric acid solutions. Line tracings of magnified fibres have given an adequate demonstration of the theory that directional felting is to be attributed to orientation of fibre units in the form of loops, in a preferred direction at right angles to that of the impulsive forces, and the anisotropic properties of felt produced by directional felting accord with this conception. A study of the physical and chemical properties of different samples and grades of lac has been commenced, and the foundations have been laid for a detailed study of wool hardening. The examination of the fastness properties of various classes of dyestuffs for fur felt indicates that the wet fastness on fur felt tends to be lower than that listed by the manufacturers for wool. The metal-complex type of dyestuff appears to possess excellent fastness properties, but in the laboratory attempts to apply them satisfactorily without undue degradation failed. Practical trials have been made of the influence of temperature in dyeing fur felt in the cone type of machine and in the free circulatory type, while studies of the effect of increases in acidity and temperature of treatment of a series of non-mercuric carrotted furs, prepared with a hydrogen peroxide–nitric acid carrotting agent, showed losses of protein remarkably similar to those for mercuric carrotted furs. Interest in the application of showerproofing agents and work on the assessment of physical properties and dimensional characteristics of felt were maintained during the year under report. An attempt is being made to separate compression from felting by studying a series of experimentally compressed felts, and an apparatus has been constructed for giving a non-destructive measure of air-permeability of wool hoods.

Computing Service at the Franklin Institute, Philadelphia

It is reported in the *Journal of the Franklin Institute* (261, 384; March 1956) that a contract has been signed for the installation of a complete UNIVAC computing centre and an integrated computation exhibit in the Franklin Institute in Philadelphia. The centre, which will be operated by Institute personnel under the supervision of Mr. D. Houghton, section chief of the Analysis Section, Division of Electrical Engineering, of the Institute, will be the largest of its kind for public use and the first to be installed in a private institution. The computations to be performed will be either for the Institute's laboratories, in which case they will relate to scientific or engineering problems, or for the public. The exhibition section will portray the historical evolution of the art of computation from the earliest calculating machine, the abacus, to the most modern electronic computer, and a guide will explain in simple and non-technical language how the ultra-modern devices operate. UNIVAC large-scale computer systems, the product of the Remington Rand UNIVAC Division of the Sperry Rand Corporation, are in use in several industrial and government institutions in the United States, and their particular value lies in the great speed of operation, the large amount of information digested and the accuracy of the results obtained because of the automatic self-checking features. In the UNIVAC computer, for example, the high-speed printer sets down the final results at the rate of 78,000 characters a minute.

Sondes Place Research Institute

The Sondes Place Research Institute has published an attractive illustrated booklet (pp. 16; from the Institute, Dorking, Surrey; 1955) describing the organization and services for sponsored research and development in chemistry, chemical engineering and mechanical engineering offered by the Institute. Some twelve hundred problems have been handled by the Institute during its first seven years, and nearly three thousand copies of its occasional bulletin, entitled "Report", are distributed in thirty-nine countries throughout the world, each issue being devoted to a single subject of general interest to industrialists and directors of research. The Institute has developed from a consulting chemical and chemical engineering practice founded in London in 1936 and incorporated as a limited company in 1947, when the present premises on the outskirts of Dorking were acquired. These include laboratories for the chemical, chemical engineering and mechanical engineering departments, a library, stores, administrative offices and drawing office. The pilot-plant house at Sondes Place has a floor area of 2,000 sq. ft., with an annexe of 700 sq. ft. for special investigations, while a further area of 1,680 sq. ft. is now available in the outbuildings of the adjacent property of Milton Heath. The services offered include technical and economic assessment of projects, laboratory research, the development of pilot plant, and the design of full-scale plant.

Museum of Applied Arts and Sciences, Sydney: Annual Report for 1954

The annual report for 1954 of the Museum of Applied Arts and Sciences, Sydney, outlines the requirements and hopes for the future of this progressive museum—probably the foremost of its kind in the southern hemisphere. Urgent needs include a new Spitz planetarium and an orrery, while the long-term policy makes provision for a new site and a new building of some 200,000 sq. ft. to replace the present one of about 27,000 sq. ft. The report states that many valuable and historic exhibits are now confined to storage, and that the limited accommodation for the public makes it almost impossible at peak periods for the exhibits to be appreciated intelligently. Exhibition activities include the display of an important collection of footwear, musical boxes and gramophones, a modern television unit and a transparent plastic woman. As usual, many scientific reports on particular problems, often of national importance, have been prepared by members of the staff.

Museum of Applied Science, Victoria: Report for 1953–54

The report for 1953–54 of the Museum of Applied Science, Victoria (pp. 15; from the Museum, Melbourne, 1955), indicates that the outstanding event was the special display arranged to commemorate the fiftieth anniversary of the achievement of powered flight. The display was in a chronological sequence and included numerous charts on the performance of aircraft, photographs, documents and relics. The exhibition included about ninety different aircraft models ranging from the age of the kite and glider to the modern period of the jet and rocket. The Fleet Air Arm displayed a Sea Fury outside the building. It is also reported that a radiocarbon dating service with the necessary apparatus is being set up by the Museum.

Turbulence above the Ozone Layer

In a paper dealing with turbulence above the ozone layer (*J. Brit. Interplanetary Soc.*, 15, 1; Jan.–Feb. 1956), Alan E. Slater gives a very comprehensive account of the subject, leading to the conclusion that the region of the atmosphere from 50 to 80 km. may not be turbulent, as is usually accepted. Discussing temperature distribution with height, patterns of convection and speed of vertical currents, he shows that there is no consistent evidence for instability in the upper regions of the atmosphere from 50 to 80 km. In addition, even if turbulence exists there, it is doubtful whether the vertical currents would be strong enough to affect significantly the passage of a winged vehicle through them. The discussion of the probable pattern of convection currents leads to the conclusion that uniform heating should give a regular pattern with the spacing between up-currents equal to two and a half times the thickness of the convection layer. Changes of wind with height in the region between 50 and 80 km. would cause the cells to be distorted and drawn out lengthwise in the direction of the wind shear, and it would be possible for a vessel flying parallel to the shear to remain in an up-current or a down-current for a long time. A discussion of the speed of the vertical currents leads to the conclusion that a winged vessel travelling at 6 km./sec. would not be affected to any noticeable extent unless the currents had a speed of several hundred metres a second. A rough calculation shows that for an up-current to reach a speed of 100 m./sec. after rising through 30 km., it would be necessary for it to be and to remain about 10 deg. C. hotter than its surroundings. It is considered unlikely that such a large temperature excess exists, and the conclusion is that there is some doubt whether the vertical currents are able to affect significantly the passage of a winged vehicle through them.

Diagnosis of Amoebiasis

An illustrated article on the diagnosis of amoebiasis, by Sir Philip Manson-Bahr (*Central African J. Medicine*, 1, No. 6; November 1955), is one of great interest to all those who have to undertake the difficult task of laboratory diagnosis of this form of human dysentery. It explains, in simple language, all the pitfalls and difficulties that await the microscopist whose duty it is to decide whether or not *Entamoeba histolytica* or its cysts are present in the material he has to examine —material which may come from the intestine, the liver, the brain or from other organs. A useful plate gives line-drawings of most of the objects that may resemble the cysts of *E. histolytica*, and other drawings show the harmless amoebae which may be present on human faeces. This is, in fact, just the kind of article that the diagnostician needs, and it gives him much detailed information that text-books omit.

Sitka Spruce and Douglas Fir in America and Great Britain

A considerable proportion of the plantations undertaken in Britain by the Forestry Commission during its early years was made with Sitka spruce and Douglas fir, chiefly the former. These conifer species come from the Pacific coast of North America. In order to make a comparison of the growth of these species in their natural habitat with that in Britain, Mr. R. F. Wood, an officer of the Forestry Commission, with the help of a Nuffield travelling scholarship, paid a visit to the forests of British Columbia and the neighbouring territories to carry out field studies, and has recorded his investigations in Forestry Commission Bulletin No. 25, "Studies of North-West American Forests in relation to Sylviculture in Great Britain" (pp. 43+35 photographs. London: H.M.S.O., 1955; 6*s.* net). A study was made of climatic zones comparatively similar to those in Great Britain from the point of view of seed collection for use in Britain. This referred more especially to the Douglas fir, which even in coastal forests occupies areas that are far more continental than those in Britain. But the results of the study showed that we still lack first-hand evidence of the advantages to be gained from close matching, and perhaps there are hints that flexibility in Douglas fir is most likely to be found in regions one step removed from the most oceanic conditions. This does not apply to the Sitka spruce, which is largely confined to regions of some oceanity and therefore more comparable to Great Britain.

Identification of an Endotrophic Mycorrhiza

An account has been given by B. Mosse (*Ann. Bot.*, N.S., 20, 78, 349; 1956) of the identification of a hitherto undescribed species of *Endogone* which she found in organic connexion with mycorrhizal strawberry roots grown in pots in a greenhouse. By inoculating sterilized soil with these fructifications and with spores excised from them, it was possible to produce typical vesicular-arbuscular infections in strawberry, apple and a number of other plants. These inoculation experiments constitute the first record of the establishment of endotrophic mycorrhizal infection in plants raised under aseptic conditions.

Oversea Service Division, Colonial Office

The following appointments have recently been made in the Oversea Service Division: J. Bowden (senior specialist, Department of Agriculture, Gold Coast), principal specialist, Department of Agriculture, Gold Coast; H. A. Darby and R. E. Osborne (senior agricultural officers, Jamica), chief agricultural officers, Jamaica; D. F. Edwards and D. R. Goodrich (agricultural officers, Gold Coast), senior agricultural officers, Gold Coast; E. J. Gregory (deputy director of agriculture, Jamaica), assistant director of agriculture, Northern Region, Nigeria; F. E. Luscombe (agricultural officer, Tanganyika), chief agricultural officer, Nyasaland; E. R. H. Martin, A. G. Naylor, R. K. Richardson and L. K. A. Swaby (agricultural officers, Jamaica), senior agricultural officers, Jamaica; W. B. Collins (senior assistant conservator of forests, Gold Coast), conservator of forests, Gold Coast; M. Dinning and D. M. Duggie (assistant conservators of forests, Gold Coast), senior assistant conservators of forests, Gold Coast; G. J. Leggat (assistant conservator of forests, Uganda), conservator of forests, Uganda; E. W. March (conservator of forests, Eastern Region, Nigeria), chief conservator of forests, Eastern Region, Nigeria; G. Webster (assistant conservator of forests, Uganda), conservator of forests, Uganda; N. J. Guest (geologist, Geological Survey Department, Tanganyika), senior geologist, Geological Survey Department, Fiji; B. O. L. Duke (medical research officer, grade III, British Cameroons), medical research officer, grade I, West African Council for Medical Research, Western Region, Nigeria; A. M. Orhan (veterinary officer, class II, Cyprus), veterinary officer, class I, Cyprus; H. Batten (senior pharmacist, Western Region, Nigeria), chief pharmacist, Western Region, Nigeria; D. R. Glendinning, scientific officer, plant breeder, West African Cacao Research Institute, Gold Coast; D. Dow, assistant cacao propagation officer, Jamaica; M. Sanders and B. M. Savory, assistant conservators of forests, Northern Rhodesia; A. E. Wright, geologist, Tanganyika; D. G. Godfrey, scientific officer (parasitologist), West African Institute for Trypanosomiasis Research, Nigeria; N. A. Hancock, veterinary parasitologist, Northern Region, Nigeria; R. M. Mackenzie, veterinary officer, Eastern Region, Nigeria; B. A. V. Peacock, curator of museums, Federation of Malaya.

Plastic Theory of Engineering Structures: Symposium in Cambridge

A SYMPOSIUM on "The Plastic Theory of Structures" will be held in the Engineering Department of the University of Cambridge during September 18–21. For twenty years a research team under the direction of Prof. J. F. Baker has been at work, at first in Bristol and since 1943 in Cambridge, investigating the behaviour of steel structures in the plastic range and developing a plastic method of designing structures. The stage has now been reached where a new branch of the theory of structures of considerable educational value is available together with a practical method of design of wide application. The symposium is therefore designed to bring together those who teach engineering and those who are practising members of the profession. The fee for the symposium is ten guineas. which will cover all living expenses, a preliminary set of the papers, and a final set of reprints, including the discussions. Further information can be obtained from the Secretary of the Department of Engineering, Trumpington Street, Cambridge.

Dilogarithms and Related Functions

MR. L. LEWIN, 33 Wellington Road, Enfield, Middlesex, writes: "I am in the course of preparing the manuscript for a book on dilogarithms and related functions and would appreciate the opportunity to appeal to readers who have encountered these functions in the course of their work. Any information on their occurrence in practical problems, and which I could incorporate, with due acknowledgment, would be welcome. The functions concerned arise from the series $\sum_{1}^{\infty} x^n/n^r$ and the integral $\int \log^n (x)\, dx/(1+x)$, and include the log sine integral".

The Night Sky in July

NEW moon occurs on July 8d. 04h. 37m., U.T., and full moon on July 22d. 21h. 29m. The following conjunctions with the Moon take place: July 6d. 17h., Venus 3° S.; July 7d. 05h., Mercury 2° N.; July 11d. 07h., Jupiter 7° N.; July 17d. 15h., Saturn 11° N.; July 27d. 14h., Mars 11° S. In addition to these conjunctions with the Moon, Jupiter is in conjunction with Regulus on July 2d. 09h., Jupiter being 0·6° N., and Mercury is in conjunction with Regulus on July 3d. 20h., Mercury 3·3° N.; also, on July 3d. 20h., Mercury is in conjunction with Venus, Mercury 3·3° N. Mercury rises at 2h. 40m., 3h. 30m. and 4h. 45m. on July 1, 15 and 31, respectively, but is too close to the Sun for favourable observation. Venus rises at 3h. 20m., 2h. 20m. and 1h. 40m. at the beginning, middle and end of the month, respectively. The close approach of Regulus, Jupiter, Venus and Mercury (though Mercury may be difficult to see) on July 3 should be an interesting phenomenon. Mars rises at 23h. 20m., 22h. 40m. and 21h. 50m. on July 1, 15 and 31, respectively, and is visible during the later hours of the night and the morning hours before twilight. Its eastward movement in Aquarius is easily detected, though it lies too low for good observation. Jupiter sets at 22h. 35m. and 21h. 45m. on July 1 and 15, respectively, but later in the month is too close to the Sun for favourable observation. Saturn lies low in the constellation Libra and towards the end of the month is a little south of γ Librae. It sets at 1h. 30m., 0h. 30m. and 23h. 30m. on July 1, 15 and 31, respectively. Occultations of stars brighter than magnitude 6 are limited to c Cap., magnitude 5·3, which disappears on July 25d. 0h. 05m., observation being made at Greenwich. The Earth is in aphelion on July 5d. 01h., its distance from the Sun being then 94½ million miles.

Announcements

THE University of Minnesota has recently made the Elvin Charles Stakman Award to Prof. W. L. Waterhouse, of the University of Sydney. This award consists of a medal, a scroll and a nominal monetary grant, and has been given for outstanding contributions to the biology of the cereal rusts and to basic concepts useful in the production of disease-resistant plants.

THE title of reader in physical chemistry in the University of London has been conferred on Dr. J. A. Kitchener, and that of reader in acoustics in the University of London on Dr. R. W. B. Stephens, both being in respect of posts held at the Imperial College of Science and Technology.

THE following awards have been made by the Lady Tata Memorial Fund for research on leukæmia and allied diseases during the academic year 1956–57: *Grants for Research Expenses*, Dr. Morten Simensen (Fibiger Laboratories, Copenhagen) and Prof. B. Thorell (Caroline Institute, Stockholm); *Scholarships* (*whole-time or part-time*), Dr. Giuseppe Marinone (University Medical Clinic, Pavia) and Dr. A. J. Therkelsen (Institute for General Pathology, University of Aarhus). Various awards made to the following in previous years (see *Nature*, 175, 1067; 1955) have been renewed for a further year: Dr. J. Kieler, Dr. J. Ringsted and Dr. J. Rygaard (Copenhagen); Dr. J. Nordmann (Paris); Dr. A. Sreenivasan (Bombay); Prof. H. G. Teir (Helsinki); Dr. C. G. V. Wasastjerna (Vasa, Finland); Dr. M. Seligmann (Paris); and Dr. Alice Stewart (Oxford).

THE seventh Canadian High Polymer Forum will be held at the Guildwood Inn, Sarnia, Ontario (postal address: P.O. Box 912, Point Edward, Ont.), during November 8–9. The Forum is sponsored by the National Research Council of Canada and by the Chemical Institute of Canada and is devoted to all aspects of polymer science. The guest speaker will be Prof. J. J. Hermans, of the University of Leyden. Abstracts and titles of papers should be sent by August 31 to the programme chairman, Dr. D. G. Ivey, Department of Physics, University of Toronto, Toronto 5, Ontario. All other communications regarding the Forum should be addressed to the chairman, Dr. H. Leverne Williams, Polymer Corporation, Ltd., Sarnia, Ontario.

ERRATUM. In a communication entitled "Muscular Dystrophy of Beef Cattle and Unsaturated Fats" in *Nature* of April 28, p. 792, the heading for col. 3 of Table 1 should read "Mean tocopherol content of milk fat (μgm./gm.)".

IMPROVEMENTS IN SEISMIC PROSPECTING

A GEOPHYSICAL Discussion of the Royal Astronomical Society was held at Burlington House, London, on April 20, when three papers were read on "Improvements in Seismic Prospecting". Mr. B. C. Browne (University of Cambridge) was in the chair.

The first communication, by F. W. Hales (Seismograph Service, Ltd.), dealt with the development and applications of continuous velocity logging. With the trend towards greater resolution and more detailed interpretations of seismic data, the need for a continuous record of seismic velocity against depth has become desirable. The continuous velocity logger has been developed to fulfil this requirement, and it has already demonstrated its ability to provide data on velocity and the delineation of reflecting horizons to such a degree as to make it a useful exploration tool.

The borehole instrument consists of an ultrasonic pulse generator and receiver suspended by a cable and separated from one another by a length of acoustic insulator. The pulses are radiated at a frequency of twenty per second, and both the times of transmission and reception are recorded at the surface. The time-delay, recorded continuously as a function of depth, is a direct measure of the seismic velocity in the materials forming the borehole walls. In addition, the recorder performs a mechanical integration of this velocity profile which gives the total time of travel from the surface to the depth of the instrument. In practice, the recorder-trace is calibrated by directly observing the time of travel from a surface shock by means of a pressure-sensitive detector fastened to the instrument.

It soon became apparent when using the instrument that it provided a picture of the lithology of the borehole walls as it concerns the seismologist, since the record demonstrated discontinuities in the acoustic impedance of the formations traversed. Hitherto, the geological log has provided a guide to the interpretation of seismic data, and the seismologist has naturally tried to associate reflecting surfaces with geological discontinuities. The continuous velocity logger reveals many discontinuities unsuspected by the geologist. From comparing such velocity profiles with the results of seismic reflexion shooting, the following observations have been made: (1) There are as many interfaces where there is a decrease of velocity with depth as there are where the reverse is true, and reflexions may originate at either type of interface. (2) Reflexions frequently originate from a group of thin layers with alternating strata of high and low velocity, the reflected signal being synthesized from the waves produced at each bed; this particular type of reflexion delineates a zone rather than a discrete interface. (3) Geological divisions established from palæontological considerations are frequently not characterized by any marked discontinuity in acoustic impedance.

Difficulties in the interpretation of seismic records caused by multiple reflexion have also been resolved by the synthesis of seismic data from the continuous velocity log. The details of this method of record synthesis have been given by Peterson, Fillippone and Coker[1]. They show that the reflexion coefficient may be approximately related to the incremental change in the logarithm of the acoustic impedance. If the assumption is made that the rock density and velocity are related by a simple power law, the reflexion coefficients may be determined directly from the continuous velocity log.

The derived record of acoustic impedance is used for calculating the amplitudes of reflected pulses, which are proportional to the reflexion coefficients; and after passing through shaping filters which simulate the absorption in the Earth and also through geophone and amplifier equivalent circuits, the recorded output has the nature of the seismic record which would be expected from the disposition of reflecting layers.

The log of interval velocity is more directly associated with the physics of the formation of layers rather than their chemistry, and it is therefore of great value to the geologist wishing to trace the lithology of a borehole. When used in a number of boreholes in the same district, it has often been possible to correlate the profiles from the separate holes. Unlike resistivity measurements, the measurements are not seriously affected by the use of highly saline drilling fluids. It has also proved possible to correlate velocity and porosity measurements within the same formation. In general, layers with low density (determined in the laboratory) have low velocities.

Work is also in progress which appears to demonstrate that when continuous velocity logging is supplemented with conventional radioactivity and electrical logs, it is possible to differentiate in some instances between the presence of gas, oil and water. In his paper, Mr. Hales showed some continuous velocity records obtained in the wells of the D'Arcy Exploration Co., Ltd., and the Compagnie d'Exploration Petrolière.

Discussing the paper, the chairman asked what ultrasonic frequency is used and whether the observed velocities are dependent on the signal frequency; Mr. P. G. Lazenby, who was joint author of the paper, said that 50 kc./s. is the pulse frequency, but no measurements have been made on the frequency dependence of velocity. Dr. T. F. Gaskell commented that measurements that have been made on coal showed no change of seismic velocity with frequency. When asked if the mud path would greatly influence the travel time, Mr. Hales said that it has been discussed, and an improved instrument is to be made having two receivers.

The second paper, read by Dr. R. Raitt, of the Scripps Institution of Oceanography, La Jolla, California, described the seismic refraction work that has been done in the equatorial Pacific Ocean on the Mid-Pacific and Capricorn Expeditions in 1950 and 1952–53, respectively. Some improvements have been made in the utilization of explosive energy for seismic waves and decreasing the noise picked up in the hydrophones. When the shot is fired at a depth corresponding to half a wave-length at the bubble pulse frequency and the hydrophones are suspended at a similar depth in a state of neutral buoyancy, the following relationship is found between the average maximum range at which signals can be observed (Δ in km.) and the shot weight (W in lb.)

$$\Delta = 7\,W^{1/2}$$

There was a wide scatter from this formula; signals have been received from an 80-lb. shot at 190 km.

In making measurements with two ships, the split-profile type of record was most often taken; the firing ship drops charges continuously and steers an approximately straight course, passing the stationary recording ship and its hydrophones at the middle of its run. The reverse profile technique was also used occasionally; but owing to drift and navigational difficulties the full value of a reverse profile was never completely realized. For the interpretation of the seismic refraction data, the assumptions of constant-velocity layers, the velocity of which successively increased with depth, were used. In addition to the topmost layers of sediment, three distinct velocity layers were observed having velocities of 4·0–6·0, 6·5–7·0 and 8–8·5 km./sec., respectively. Changes in these velocities in a lateral direction were observed; but whether these are always real is uncertain. The velocity in the upper sediments was not determined by refraction; but a few reflexion measurements gave an average at 2·15 km./sec.

Dr. Raitt presented a slide showing the thickness of the crust defined by the depth at which the velocity reaches 8 km./sec. as found by several workers on the continents and by his work in the Pacific Ocean. The mean thickness for the Pacific Ocean is about 6 km., which contrasts with the 30 km. for the continents.

Questioned on the dependence of arrival time on frequency, Dr. Raitt said that only at short distance was it possible to observe waves of different frequency travelling over the same path. In these cases, no dependence on frequency was observed. When asked by the chairman if he had any views on the composition of the layer below the unconsolidated sediments, Dr. Raitt said that it is in doubt whether they are volcanic or sedimentary. The answer to this problem would tell us much about the history of the oceans. If the 4·0–6·0 km./sec. layer is lithified sediment, the oceans are probably very much older than would be expected if the layer were igneous.

Dr. S. Wyrobek (British Petroleum Co.), who read the third paper, said the refraction method has been used in some areas to give a fairly comprehensive picture of the variation of velocity in both the lateral and vertical directions and to reveal sub-surface structural features. It is known that the method is most successful where velocity contrasts are pronounced, but it has been perfected to the extent of delineating layers where the velocity contrast is less than 2,000 ft./sec.

The guiding principle in deciding the disposition of geophones and shots is to cover continuously all the important refractors in the area and especially the shallow refractors, since these greatly influence the shape of the deeper layers. A refraction line consists of several spreads. Each spread may have twenty-four geophones 250–1,000 ft. apart and several main shot points outside the spread at distances of 5,000–10,000 ft. At each geophone station or every alternate one, smaller shots are fired, which elucidate the weathered layer and any low-velocity layers. Continuous time profiles are obtained in both directions of shooting, and these are used for obtaining half-intercept time values and hence the values of the refracting velocities and their lateral variations. By the method of interpretation used, individual refractors are discriminated by ensuring that the reciprocal times are equal, that the intercept times match in each direction of shooting, and that both the direct and reverse time profiles match the half-intercept time values if one deals with the same refractor.

The aim of the method is first to convert the time–distance curve into a time section, that is, into a section in which the vertical scale gives the delay-time of a point on the refractor below the datum; this is achieved by producing the so-called half-intercept time profiles. From the latter, by using information obtained from well surveys or assuming the seismic velocities determined for the upper refractors to be uniform in a vertical direction, or introducing a velocity distribution characteristic of the area, a depth profile for each refractor is easily obtained.

Mr. D. R. Brown asked what velocity variations and dips could be encountered before the method broke down, to which Dr. Wyrobek replied that the complications would appear where lateral variation of velocity along a refractor approached the variation in the vertical direction. The method has proved satisfactory in areas of dips up to 8°. It will be published in a subsequent number of the *Geophysical Prospecting Journal of the European Association of Exploration Geophysicists*.

ELECTRICAL EQUIPMENT OF AIRCRAFT

THE convention, as a means of bringing to a focus widely scattered knowledge of a particular subject, has gained a great deal of popularity in recent years, and that on "Electrical Equipment of Aircraft", held in London at the Institution of Electrical Engineers during May 2–4, proved to be no exception; the accommodation of the lecture hall of the Institution was strained to the utmost, and additional chairs were placed wherever possible. The chair at the opening session was taken by the president of the Institution, Sir George H. Nelson, and the proceedings began with a short address by the Minister of Supply, Mr. R. Maudling.

Mr. G. R. Edwards, general manager and chief engineer (aircraft) of Vickers-Armstrongs, Ltd., followed with a most entertaining talk, in which his humorous sallies provided some light relief for the serious matter of his address, which was the problem of the aircraft designer, wishing and indeed compelled to use electricity to an ever-increasing extent for a multitude of purposes in connexion with the functioning of the aircraft, and yet faced with the reduction of useful load-carrying ability involved in the weight and drag of electrical equipment and its cooling auxiliaries. The only electrical equipment on the earliest aircraft was a magneto generator to supply the ignition system, and this was both light and reliable. Modern large civil and military aircraft are equipped with about 150 kW. of electrical power and, with developments likely in the near future, the power provided may rise to 400 kW., or even, according to some estimates, to 700 kW. The weight of the equipment, with the additional fuel required to drive it, is of the order of 3 per cent of the total aircraft weight. If the pay-load of a civil aircraft is 10 per cent of the total aircraft weight, the electrical equipment reduces the pay-load by one-quarter, and the importance of saving weight is apparent.

Important as it is to save weight, it is still more important to achieve reliability. Moreover, the increase in speed and flying height of modern aircraft introduces new problems of cooling and brush-wear which are generally adverse to saving weight. The designer is at a disadvantage compared to his land-based colleagues in every respect except cost, which he may largely ignore if a saving in weight may be achieved by the use of costly materials or special apparatus.

Nineteen papers* were presented at the convention covering the uses of electrical power, the means to obtain it and the methods and equipment necessary to obtain reliability. The last session was devoted to a discussion of the problems of installation and maintenance, which often influence the choice of equipment for a particular aircraft.

The importance of weight-saving would appear to justify the design of the electrical equipment as a single unit, each element being planned to give minimum total weight to the equipment rather than to have minimum weight itself. This ideal has not yet been achieved, and the choice of supply system, for example, is often governed more by the availability of consuming apparatus of a given design than by a rigid assessment of the optimum system for minimum weight.

The most popular generating systems at present are 28 volts and 112 volts d.c., and 200 volts three-phase a.c. with 115 volts between line and neutral. The frequency of a.c. supplies may be variable from 200 c./s. to 500 c./s. according to engine speed; or generation may be achieved at a fixed frequency of 400 c./s., 1,600 c./s. or 2,400 c./s. either by a differential speed drive between the engine and the generator or by a separate power unit. It is unfortunately not practicable to design all consuming apparatus to operate from the same supply system; and, whichever system is adopted, means have to be provided, usually by additional motor generator sets, to provide auxiliary supplies.

The 28-volt d.c. system is popular on account of ease of maintenance and reliability. Fewer cells are required in a standby battery, and heater filaments for this voltage are of adequate section so that they fail less frequently. Transmission losses and the weight of cable required become serious in large aircraft, although this aspect is complicated by the large number of cables the dimensions of which are fixed by considerations of mechanical strength rather than by current-carrying capacity. Aluminium conductors offer the possibility of reduced weight for the same current-carrying capacity, but at the expense of increased volume. It is not always practicable to accommodate the larger aluminium cable.

The 112-volt d.c system generally yields a reduction of weight both of the generators and of the cables, although the reduction of weight is not as striking as might be expected, since the additional insulation increases the weight of cables of minimum section.

The a.c. systems gain flexibility from the use of transformers; but the transformer weight is not economically used in the variable-frequency system. Moreover, some constant-frequency supplies are necessary for some of the consuming apparatus, and this has to be provided by motor generators. These additions of weight have to be balanced against the reduction achieved by a direct engine drive. The constant-speed hydro-mechanical drive or the auxiliary power unit to give constant frequency is gaining in popularity.

A serious problem for high-altitude flying is brush wear. This problem is less serious with slip-rings than with commutators, so that a.c. supplies have an advantage in this case. The development of satisfactory silicon rectifiers which can be operated at higher temperatures than germanium rectifiers makes possible the design of brushless alternators and also enables d.c. supplies to be obtained with a reasonable weight penalty from a.c. generators.

The most popular frequency system is 400 c./s. Transformer weights are reduced at the higher frequencies; but this advantage is counterbalanced to some extent by increased eddy-current losses in cables. The higher frequencies may be essential for some consuming apparatus.

The cooling of electrical equipment is a major problem, especially at high altitudes and speeds. Designs of minimum weight of electrical equipment tend to be inefficient, and this increases the weight of cooling equipment and the drag it exerts on the aircraft. In many cases, it is preferable to increase the efficiency of the electrical equipment at the expense of its weight in order to reduce the cooling problem. So far as practicable, engine fuel should be used for absorbing heat: additional cooling is usually air cooling, either by natural convection and radiation, or by blast cooling. Limits are set by ambient air temperature which rises with the speed of the aircraft on account of adiabatic compression at the intakes. When the ambient air temperature is higher than that of the electrical equipment, refrigeration must be employed in order to dissipate the heat.

Striking developments of batteries have taken place in the search for weight reductions. The lead–acid battery has been reduced about 40 per cent in weight by improved materials and construction, while the newly developed nickel–cadmium battery and zinc–silver oxide battery give a better discharge performance than the lead–acid battery.

Finally, the smooth functioning and reliability of the equipment is vitally dependent on satisfactory frequency and voltage regulators and on a good protection system, including adequate switchgear. Switch performance is generally adversely affected at high altitudes by the change in the arc characteristics; although research has shown that this deterioration is not as severe as early experiments had suggested, it is clear that alternating currents are likely to be more easily interrupted than direct currents, and this is a further argument in favour of the a.c. system.

Bird, D. C. Hancock and D. B. McKenzie: aircraft electrical cables. C. W. Cooper: the development of voltage and frequency regulators for aircraft electrical systems. G. A. Earwicker: aircraft batteries and their behaviour on constant-potential charge. A. H. M. Arnold and L. H. Ford: d.c. circuit interruption and arc characteristics at low air pressures. I. A. Mossop and F. D. Gill: the current and voltage relationships of a stable d.c. arc between copper and silver electrodes in air at 1–760 mm. of mercury. N. C. Adcock and A. W. Ford: excitation systems for a.c. aircraft generators.

Most aspects of aircraft electrical equipment were thoroughly covered by the papers presented, and these, together with the discussions on them, should provide a useful work of reference for those concerned with the design or utilization of such equipment. An interesting point made was concerned with the adverse effect of standardization on the weight of electrical equipment, and a plea was entered for an increase in the number of standard sizes in order to reduce the weight penalty.

MARINE BIOLOGY

SYMPOSIUM AT THE SCRIPPS INSTITUTION

A SYMPOSIUM on "Perspectives in Marine Biology" was held in the Scripps Institution of Oceanography, La Jolla, California, during March 24–April 2, under the auspices of the International Union of Biological Sciences and jointly sponsored by the University of California and the Office of Naval Research of the United States Navy. Owing to generous financial help and to the co-operation of the Military Air Transport Service of the United States, a large and representative body of marine biologists attended from all parts of the world, eight being from Great Britain. The programme of prepared papers covered the whole range, and indeed more than is usually regarded as the whole range, of the composite science of marine biology. Certain of those invited to participate came to give accounts of work of very wide biological implication, and they also made major contributions to the discussions which followed the papers. Very adequate provision had been made in the time-table for such discussions.

It is undoubtedly true to say that no such broad survey of the field of biological investigation in the marine environment has hitherto been held. Observation and discussion ranged from the factors of the marine environment to the study of bottom fauna and of plankton communities, through problems of biochemistry and regulation, both chemical and in respect of timing and rhythms, to problems of production and productivity, notably in relation to both phytoplankton and bacteria. The importance of ethology was stressed, and both the sensory equipment and effector mechanisms of marine organisms were discussed. Problems of speciation and of genetics formed the subject-matter of the concluding sessions of a programme that had been organized by Prof. A. A. Buzzati-Traverso, to whose distinction as a geneticist must certainly be added high ability as an organizer.

An experiment of great interest was made during the symposium, the participants in which were organized into a series of 'idea groups' of very mixed membership where the subject-matter of the papers and general matters appertaining to marine biology were informally discussed. The concluding session of the symposium took the form of a meeting at which spokesmen of the various groups gave some account of their deliberations and answered certain leading questions which had been put to them. In the opinion of the writer, himself one of the spokesmen, profitable use could probably be made of such a scheme in future, although perhaps in this instance both subject-matter and participants were somewhat too heterogeneous. A doubt was left as to whether those who organized the symposium would obtain any major lead from the deliberations of the idea groups.

But there can be no doubt that, as a result of the discussions, both formal and informal, all who attended the symposium left it with increased knowledge both of their science and of their colleagues from many countries. Regret was widely expressed at the absence of the delegates expected from the U.S.S.R. The Scripps Institution of Oceanography now has the possibilities, through a major grant of money from the Rockefeller Foundation, to develop greatly the biological aspects of its work. Those responsible for the symposium must certainly have gained an idea of the extent and diversity of modern investigations in marine biology. The majority of these, outside the field of fishery research, are the achievements of individual workers, although naturally such work is being increasingly aided by the facilities of modern marine biological laboratories and research vessels. Along what lines of research money might most fruitfully be spent would, at this stage, seem to depend more on the quality of the people employed than on the actual programme, and it is to be hoped that the Scripps Institution will be successful in its endeavours to obtain workers of the highest quality to develop its biological programme.

C. M. Yonge

SCIENTIFIC HUMANISM

It is a commonplace of discussions on the universities that there is an ever-widening gap between the arts and the science graduates: this usually takes the form of a most often unjust attack on the 'narrow scientist'. S. J. Tester, a lecturer in classics at the University of Bristol, suggests that the 'narrow arts graduate' is a commoner phenomenon and represents a more serious problem (*Univ. Rev.*, 28, No. 2; Feb. 1956).

Most graduates in one of the special sciences will, in a time of films and theatres, radio and television, "Penguins" and "Pelicans", imbibe something of what the arts man so often describes as 'culture'; but most arts graduates leave the universities with practically no conception of the revolution that took place in science between the seventeenth and nineteenth centuries, and the further revolutionary developments which have occurred since 1900. Unfortunately, they leave not feeling ashamed of this ignorance but either proud of it or indifferent to it; they consider it irrelevant to their being 'cultured' or 'educated'. Tester suggests a way in which both these problems—that of the science graduates' lack of contact with the minds of the great thinkers of the past and that of the arts graduates' blindness on the side of science—might be at least partly solved.

The way in which the universe in all its physical aspects is now regarded is largely due to developments in science between the seventeenth and nineteenth centuries; it is to be expected that new developments in physics, physiology, psychology and electronics will produce changes in men's commonplace opinions in the future. It is possible to draw up a list of half a dozen or so books which would epitomize the 'scientific revolution', all, or nearly all, books written for the educated public of their day by men of generally acknowledged genius or importance, and all readable by any intelligent student.

A suggested list is: Harvey's "De Motu Cordis" (1628); Galileo's "Dialogue concerning the Two Chief World Systems" (1632), selections; Boyle's "Sceptical Chymist" (1661); Newton's "Principia" (1687), selections, but at least the early chapters of Books 1 and 3; John Ray's "The Wisdom of God" (1691); James Hutton's "A Theory of the Earth" (1785), or possibly selected parts of Lyell's "Principles of Geology"; Darwin's "Origin of Species" (1859); Einstein's "The Theory of Relativity" (1926). All university students, whatever their faculty, should be required to read these books and to take an examination on them at the end of the first term of their final year.

Such a course of reading would not be intended to make science students philosophical, nor to introduce them to the philosophy of science. It would give them real contact with greatness, such as the classic student has in reading Aeschylus or the philosophy student in reading Kant.

There is no question here of 'broadening' the scientist, of providing a humanist background for his studies. Nor is this proposal intended to provide the arts student with an outline of modern science or a 'potted' history of science. The way in which the scientist, and even the ordinary non-scientist, regards the physical universe has been largely determined by these works or the movements they epitomize; to think as we do and yet be ignorant of them is like being ignorant of the teachings of the New Testament while living in a Christian society.

Most of these are very old books, and much of their matter is long out of date. It would therefore be necessary to explain to what degree the facts and theories given in these works are still accepted, and how far they have been modified or discarded. It would also be necessary to make it plain to the students precisely why these works are important. This would mean putting each in its context, describing the state of each particular science before the work in question, the revolution affected by it, and its influence and importance in later scientific thought. This could be done in a course of lectures; but Tester believes this could be better done in a book prepared by experts in the several fields.

ECOLOGICAL ANALYSIS OF THE INTERBREEDING OF CRESTED TITMICE IN TEXAS

ECOLOGY and behaviour during the early phases of the nesting cycles have been compared by Keith L. Dixon in two superficially distinct forms of titmice. A grey-crested bird, the tufted titmouse (*Parus bicolor*), is a characteristic inhabitant of deciduous forests of the humid eastern United States. Its distributional-range meets that of the black-crested titmouse (*Parus atricristatus*) at a few points in central Texas. The latter bird is found commonly in openly spaced plant associations of arid north-eastern Mexico and adjacent parts of Texas. Interbreeding occurs wherever populations of these non-migratory forms are in contact.

Field work in central and western Texas was carried out during February–April 1951 and in January and February 1952. Each of the forms was studied first in areas remote from any influence of the other form; this study was used as a basis for evaluating conditions in areas where interbreeding was known to occur (University of California Publications in Zoology, 54, No. 3).

Tufted and black-crested titmice are similar in their habitat relations, especially in nesting requirements and foraging. The preferred habitats of these birds merge at the points of contact which lie in a transition from humid to arid climates. The call notes of the western form seemed louder and more nasal, and the songs were of longer duration. The only difference in display was the more erect carriage of the crest in the black-crested form. As the nesting cycle advanced, tufted titmice tended to be more secretive, whereas black-crested pairs were not so difficult to locate. Defence of territory appears more vigorous in the tufted titmouse. These differences in behaviour are more apparent later in the breeding cycle than they are at the time when pair formation is believed to occur. Detailed studies in the field, correlated with examination of specimens, suggests that mate selection is random where the populations overlap. No evidence of reduction in the vitality of birds of intermediate character was found. The evidence suggests that these two varieties diverged from a common ancestor, but that the changes which developed were not accompanied by the evolution of mechanisms which would ensure reproductive isolation. Since free interbreeding between black-crested and tufted titmice occurs, Dixon suggests that they should be considered conspecific.

The three principal areas where contacts between populations of the two kinds of titmice exist or have existed were studied. In each area the junction was permitted by extension of woodland vegetation across prairies otherwise uninhabitable by these titmice. The upland timber of these areas is controlled by factors operating through the soil. This fact points to the permanence of the distributional relations, and the suggestion is made that the interbreeding of these titmice antedates the environmental disturbances brought about by the settlement of Texas by the white man.

The genetic constitution of one intermediate population, near the Aransas River, is shown to have changed towards that of the black-crested during the past century. The spread of woody vegetation is believed to have favoured the increase in numbers of titmice of the black-crested type in this area, and hence to have permitted increases in frequency of its genes in the intermediate population, while the contribution from the grey-crested populations was being reduced.

STANFORD RESEARCH INSTITUTE, CALIFORNIA

REPORT FOR 1955

THE report of operations for 1955 of the Stanford Research Institute, California*, records an increase in staff from 914 to 1,163, of whom 630 have technical training and 125 Ph.D. degrees. Contract research is being conducted at the rate of 10 million dollars a year, and in the nine years of the Institute's existence has totalled about 35 million dollars. Of the 532 research projects undertaken in 1955, 132 were for government agencies; but in terms of dollars the ratio of commercial projects to government projects was 56·6 : 43·4. Following a final decision as to the site, rapid progress was made in developing building programmes for offices and research activities. The Associate Plan was further extended, and by the end of the year 116 firms or individuals had pledged or contributed one or more units of 15,000 dollars, totalling 2,266,525 dollars, to this fund for improving the Institute's research facilities.

---

* Stanford Research Institute. Report of Operations, 1955. Pp. 47. (Menlo Park, Calif.: Stanford Research Institute, 1956.)

Progress was made in the solar energy programme, including a study by the Institute of flat-plate collectors, in which a solar-heat pump from the Somor Company of Italy was used, studies of the feasibility and design of extremely large solar furnaces for high-temperature research, and the production of a directory and bibliography of research in this field. A reflector-type furnace for temperatures in the range 2,000°–3,000° C. has been designed which can be used interchangeably with three sources of radiation-solar, flame and the electric arc. A feature of the activities during the year in this field was the international symposium on applied solar energy, held in Arizona during November 1–5. A new phase of activity in the field of nuclear energy was to assist companies contemplating entering this field by evaluating possible markets and analysing the need for development work and associated manufacturing, marketing and financial problems. A Nuclear Energy Service was established to provide a source of up-to-date information on developments, and a study of the most suitable design of industrial reactor led to the selection of a reactor of the heterogeneous type, moderated by heavy water, with a 10-MW. heat output and a maximum neutron flux density of 2×10^{14} neutrons sq. cm./sec. Its power-level is at least ten times that of most research reactors, and it is proposed that the co-operative reactor laboratory should be owned by a non-profit corporation, subsidiary to the Institute, and that the reactor would also be available for use on a contract basis for applied research. Nuclear engineering studies included radiation studies of food products and of chemical reactions induced by radiation, while the possibilities of radiation as an industrial tool were being explored.

An extensive study was made of the research needs of the forest industries, particularly of the West, and in a new physical sciences laboratory reactions of hydrocarbons and their derivatives were being studied at pressures up to 10,000 lb./sq. in. in a new type of reaction chamber providing complete operating safety at low test. A new wing in the chemical engineering laboratory contains high-temperature electric furnaces, a spray dryer, a high-pressure air system and kindred equipment for the development of high-temperature alloys and other materials. The enlarged laboratory is also being used for trials of new processes on a scale sufficient to provide information for the design of pilot plant. In a classified study of ballistic and physical properties of solid propellants, special equipment has been provided for measuring the rate of burning of propellants in strand form, ignition time, and tensile strength at high rates of strain application. The television and vacuum-tube laboratory has been approximately doubled in capacity and has been concerned with research on video recording, the more efficient utilization of television channels and industrial applications of television techniques. From a study of existing air-modulated loudspeakers and of the principles and factors affecting efficiency, the Institute has been able to design a prototype loudspeaker—the Stanford airstream modulator—costing about a fifth as much to build as other units of this type, with about 80 per cent of the theoretical efficiency and which, with only 10 watts of air energy and 10 watts of air control, can be heard about 1·5 miles away. The addition of a new electronic computer greatly increased the ability of the Computation Centre to handle large problems, and in a single afternoon an operations research team obtained data on a complex study of the most economic method of dispatching empty freight cars that normally would have taken one man two years to procure. New equipment has also been installed in the control-systems laboratory for studies of surface physics and materials, and a new laboratory established for research on special problems in the graphic arts. The Poulter laboratories have made contributions to the understanding of detonation and hydrodynamics of shock-pulse phenomena, with consequent severalfold improvement in the efficiency of military and civil explosives, and are also engaged in combustion and general high-pressure research. An irradiation study initiated by the Sequoia Process Corporation led to a new type of polyethylene resistant to 150° C. and suitable for high-temperature application in aircraft and electronics; and, with the Bank of America, the Institute has designed an electronic recording machine which automatically does all checking of customers' accounts.

FUTURE NUMBERS OF UNIVERSITY STUDENTS IN BRITAIN

AN address on the number of university students, which Lord Simon of Wythenshawe delivered to the Court of the University of Manchester on November 16, was afterwards published in a revised and extended form in the February issue of the *Universities Quarterly*, and a reprint of this article has been issued entitled "Future Numbers of University Students: the Desperate Need for Technologists"*. In his original address, Lord Simon discussed separately both the national problem and the particular contribution Manchester could be expected to make alike in respect of the general need for expansion and the shortage of technologists; he expressed the view that no expansion should be contemplated at Manchester beyond the five thousand students for which the new buildings would provide, except that, in addition, the College of Technology should expand to reach a student population of fifteen hundred within a decade. In the pamphlet now issued, Lord Simon looks at the question of student numbers purely from a national point of view and, after reviewing the expansion since 1911, considers more particularly the measures which should be taken to meet the situation likely to arise in the next ten years. He assumes that university standards will not be raised, that the universities will continue to accept approximately the present proportion of sixth-form pupils and that accordingly they will expand to the extent necessary to admit the increased number of those attaining present standards which will be forthcoming when the increased population passing through the schools reaches the university stage from 1962 onwards. He estimates that entrants in 1965 are likely on these assumptions to be 40–100 per cent above the present level, and that it is imperative to begin at once to erect the necessary buildings.

---

* Future Numbers of University Students: the Desperate Need for Technologists. (Reprinted from *Universities Quarterly*, February 1956.) By Lord Simon of Wythenshawe. Pp. 15. (London: Turnstile Press, Ltd., 1956.) 1*s*.

Lord Simon lays his main stress on technology. Pointing out that the number of degrees and diplomas in technology awarded by the universities in Great Britain has been decreasing since 1950 (from 3,593 to 3,359), he emphasizes that both the U.S.S.R. and the United States are already producing each year about twice as many graduates in science and technology per thousand of population as Great Britain, and that in the U.S.S.R. the output during the past five years has increased by more than 10 per cent a year. The Federal Institute of Technology at Zurich, he points out, has at present 2,700 full-time degree students, which is more than the three largest technological institutions in Britain put together, and the totals of 3,600 and 3,400 graduate engineers produced in Britain in 1950 and 1954, respectively, compare with 50,000 and 20,000, respectively, in the United States and 28,000 and 54,000 in the U.S.S.R. He urges that the rate of building for universities should be increased at once to provide reasonable accommodation for a 50 per cent increase in the number of students by 1965, and immediate and energetic action should also be taken to increase the output of graduates in technology by 10 per cent a year, with an ultimate output of at least ten thousand engineers a year. As a contribution to this end, he suggests the appointment of a small Royal Commission to report on the situation within six months.

MATING SYSTEMS OF FUNGI

In a paper under this title, J. H. Burnett (*New Phytol.*, 55, 1, 50 ; 1956) has attempted to classify the principal kinds of mating systems, to devise an appropriate terminology for them, and to describe how they operate and are controlled. He points out that, so far, there is no adequate and agreed terminology for describing fungal mating systems.

The terminology now proposed includes the following. Under the term 'heteromixis', he would include those instances, or imply the condition, where sexual reproduction only results from the fusion of genetically different nuclei normally derived from different thalli. Heteromixis includes : (1) 'dimixis', the condition where there are two, and only two, types of complementary nuclei which control mating, the nuclear types being determined by two allelomorphs at a single locus ; (2) 'diaphoromixis', the condition where several types of complementary nuclei occur which control mating, the nuclear types being determined by multiple allelomorphs at one or two loci, the bipolar and tetrapolar conditions, respectively ; and (3) 'homo-heteromixis', this being an essentially heteromictic condition where sexual reproduction results only from the fusion of genetically different nuclei derived normally from the same thallus ; such forms are derived from dimictic or diaphoromictic forms, hence the derived terms, 'homo-dimictic' and 'homo-diaphoromictic'.

'Homomixis' is defined as the condition where sexual reproduction can result from the fusion of genetically similar nuclei, these being usually derived from the same thallus. 'Amixis' is defined as the condition where the essential events of sexual reproduction are lacking but where the pre-conjugation and post-meiotic events normally associated with sexual reproduction may occur. The author prefers this term to 'apomixis' since the condition described is one in haploid organisms. It is so defined as to cover a wider range of conditions than does apomixis as used for conditions in higher plants. The author describes how the principal mating systems operate, and concludes that the factors which control compatibility are pleiotropic in their effects. This suggests that mating-type factors are, in fact, groups of closely linked genes.

From a review of the evolution of mating systems, he concludes that it is not possible at present to give a general account of this phenomenon. It is, however, possible to make suggestions concerning the origin and evolutionary processes involved in some of the systems, and some hypotheses are developed. A general conclusion is that mating systems have arisen in a variety of ways and that, in the first instance, selection of potential mating-type factors may not have been for their effects upon compatibility.

RESEARCHES IN THE ARCTIC OCEAN

The arctic, up to the North Pole, might be an open sea for part of each year if it were not for the piling up of pack ice into thick ridges by storms. Otherwise, ice formed during the intensely cold winter nights would be thawed completely by September. This speculation is advanced by Prof. G. E. MacGinitie, of the California Institute of Technology, in a technical report on arctic life just published by the Smithsonian Institution. Prof. MacGinitie was principal investigator at the Navy's Arctic Research Laboratory at Point Barrow, Alaska. It is highly improbable that the sea surface as a whole ever freezes during the winter to a depth of much over 6 ft. Thousands of lakes and ponds in the country behind the arctic coasts freeze to depths of more than 7 ft., yet this ice melts entirely during the summer.

During the storms of gale force that sweep over the arctic basin, the surface ice is piled up into windrows which may be several times 6 ft. thick. These drift together and constitute the great arctic pack. Summer melting is more than compensated for by the increased thickness of windrowed ice. Ice over offshore areas which has not been piled up by wind and wave disappears completely by September. The movement of the ice pack itself may have some influence on animal distribution. This pack constitutes about 70 per cent of the arctic ice. It is never stable. Previous investigations have shown that it may move as much as 1,000 miles in nine months. There is good evidence, Prof. MacGinitie says, for considering the pack as a great, moving field, the general direction of which is from north-east Siberia to the east of Greenland.

Prof. MacGinitie has also made some observations about Eskimo life.

The Eskimo birth-rate is increased as much as threefold when the arctic people eat "white man's food" instead of their traditional pure animal diet of whale, fish and seal. When hunting was the only means of subsistence, Eskimo women became pregnant only once in several years; but with the new diet they bear a baby about every year.

Of primary importance in the old Eskimo culture is the bowhead whale. Several are taken in the spring of each year and the flesh stored underground in cellars, where it remains edible for three or four years. The whales feed on euphausiids, mysids, pteropods and copepods. Baleen whales probably lead the easiest life of any mammal. These enormous creatures have only to swim slowly through water, which has about the same specific gravity as themselves, opening and closing their mouths and swallowing food. To an Eskimo the most delectable food is whale muktuk, which consists of whale skin with about an inch of underlying blubber. After freezing, the muktuk is cut into small pieces and eaten raw. Next in importance in the native economy is the bearded seal. This marine animal, which reaches a weight of 500–600 lb., feeds almost entirely on amphipods. In winter these seals are hunted in offshore leads. Unlike most seals, they float when shot, so they can be taken easily. In summer they are hunted in boats.

ANAEROBIC DEAMINATION OF D-GLUCOSAMINE BY BACTERIAL AND BRAIN EXTRACTS

By DR. P. FAULKNER* and PROF. J. H. QUASTEL, F.R.S.

McGill-Montreal General Hospital Research Institute, 3619 University Street, Montreal

THE discovery that D-glucosamine is phosphorylated by adenosine triphosphate in the presence of brain hexokinase[1] and of yeast[2], glucosamine-6-phosphate being produced[2,3], and the demonstration[4] that competition may take place between glucose and D-glucosamine in metabolic events in the cell, led to investigations[5] on the possible inhibitory influence of D-glucosamine on the growth of cells developing at the expense of glucose breakdown. While D-glucosamine proved to be an inhibitor of growth of sarcoma 37[6], and of human epidermoid carcinoma[7], in tissue culture, it is ineffective in suppressing tumour growth in animals and man, though a positive effect was once reported[5]. The failure of D-glucosamine to act as a tumour inhibitor *in vivo* seems to be linked with its relatively rapid breakdown in the body. For this reason, experiments have been carried out to learn the details of D-glucosamine degradation in the cell. This phenomenon has been the subject of investigations by Lutwak-Mann[8], who studied the metabolism of D-glucosamine in presence of animal tissues, yeast and bacteria, and by Rosenberg[9], Rogers[10] and Oka and Murachi[11], who have studied the degradation of D-glucosamine in presence of bacteria. Biosynthesis of D-glucosamine has been demonstrated by Leloir and Cardini[12], who have shown that an interaction of hexose-6-phosphate and glutamine takes place in presence of extracts of *Neurospora crassa* to yield D-glucosamine-6-phosphate and glutamate.

Our experiments have been directed to an investigation of D-glucosamine deamination and have been carried out with extracts of *E. coli* and of brain tissue. The following is a preliminary statement of the results that have been obtained; full details will be published elsewhere. Many of the findings presented here have been reported in a thesis by one of us[13].

About 3·5 gm. wet weight of *E. coli* grown overnight in a yeast extract – peptone medium, and washed with distilled water, using a Sorvall high-speed centrifuge, were crushed in a Hughes bacterial press[14] which had been cooled to –20° C. The frozen crushed material was extracted with 20 ml. water. The debris was removed by high-speed centrifuging in the cold, and the cell-free supernatant was used for the study of D-glucosamine breakdown. Brain tissue extract was prepared by centrifuging in the cold, for 10 min. at 20,000 *g*, a rat-brain homogenate made up in isotonic potassium chloride solution (1 gm. brain tissue to 10 ml. potassium chloride), the supernatant being used as the D-glucosamine deaminating enzyme system.

Incubations were carried out in the conventional Warburg manometric apparatus at 37° under anaerobic conditions, the gas phase being a mixture of 93 per cent nitrogen and 7 per cent carbon dioxide. D-Glucosamine was estimated by a modification of the method of Elson and Morgan[15], ammonia by the method of Braganca *et al.*[16], hexosediphosphate by that of Roe[17] and phosphates by that of Fiske and Subbarow[18]. Sugar phosphates were separated by paper electrophoresis (Durrum[19]), the dried papers being sprayed with the aniline hydrogen phthalate reagent of Partridge[20] to detect the position of the sugars.

Deamination of D-glucosamine and N-acetylglucosamine takes place anaerobically in an extract of *E. coli*, the process being dependent on the presence of adenosine triphosphate and magnesium ions. Little or no breakdown of D-glucosamine takes place in the bacterial extract under anaerobic conditions; in the presence of adenosine triphosphate, however, utilization of glucosamine may be readily demonstrated. For example, 2·8 μmoles of D-glucosamine were removed from the system when 10 μmoles of the amino-sugar were incubated anaerobically with 1 ml. of *E. coli* extract at 37° C. for 45 min. in the presence of 6·7 μmoles adenosine triphosphate. Further results, in which the rates of deamination of D-glucosamine and N-acetylglucosamine are compared, are shown in Table 1. They demonstrate that glucosamine is deaminated at a slower rate than N-acetylglucosamine; but when mixtures of glucosamine and N-acetylglucosamine are incubated with adenosine triphosphate, a more than additive rate of ammonia production takes place.

---

* Present address: Laboratory of Insect Pathology, Sault Ste. Marie, Ontario, Canada.

Table 1. DEAMINATION OF D-GLUCOSAMINE AND N-ACETYL-D-GLUCOSAMINE IN THE PRESENCE OF *E. coli* EXTRACTS

Present: bicarbonate, 0·028 *M*; magnesium sulphate, 0 0033 *M*; *E. coli* extract, 1 ml. Where added. sodium adenosine triphosphate, 0 0033 *M*. Total vol. 3 ml. Incubation time, 55 min.

	Ammonia formed (μmoles)	Ammonia formed from amino-sugar (μmoles)
Exp. 1		
Adenosine triphosphate	2 2	0

The virtual necessity of the process of anaerobic deamination of D-glucosamine for adenosine triphosphate makes it likely that the substrate for deamination is D-glucosamine-6-phosphate. A similar conclusion applies to the anaerobic deamination of N-acetylglucosamine, the phosphate ester of which is also formed in the presence of adenosine triphosphate and *E. coli* extract.

Soodak[21] has recently noted that extracts of *E. coli*, prepared by sonic rupture of the cells, phosphorylate D-glucosamine and N-acetylglucosamine in the presence of adenosine triphosphate and magnesium ions.

It is easy to demonstrate by the manometric technique[1] that dialysed *E. coli* extracts bring about the phosphorylation of glucose and D-glucosamine in the presence of adenosine triphosphate, the same hexokinase being apparently involved as shown by competitive experiments. The phosphorylation of N-acetylglucosamine requires a separate kinase as shown by the additive rate of phosphorylation which is exhibited when a mixture of glucose and N-acetylglucosamine is incubated in the presence of an *E. coli* extract and adenosine triphosphate.

Glucosamine breakdown in an *E. coli* extract is inhibited by the presence of glucose. Thus, the addition of 0·01 *M* glucose to a system containing 0·005 *M* D-glucosamine, 0·0005 *M* N-acetylglucosamine, 0·003 *M* adenosine triphosphate, 0·003 *M* magnesium sulphate and *E. coli* extract brought about almost a complete cessation of the disappearance of D-glucosamine. This phenomenon is doubtless due to competition between glucose and D-glucosamine for the same hexokinase. Lutwak-Mann[8] and Oka and Murachi[11] have reported that glucosamine deamination by resting *E. coli* is inhibited by a number of sugars.

Adenosine triphosphate cannot be substituted by adenosine-5-phosphate for the anaerobic deamination of D-glucosamine in an *E. coli* extract (Table 1). A mixture of acetyl phosphate and adenylic acid, however, can effectively replace adenosine triphosphate.

The D-glucosamine anaerobic deaminating system in *E. coli* is unaffected by the presence of either diphosphopyridine nucleotide or by L-glutamate or by pyridoxal phosphate.

Electrophoresis on filter paper of a mixture of D-glucosamine, a trace of N-acetylglucosamine, magnesium ions, adenosine triphosphate, and dialysed *E. coli* extract, after anaerobic deamination at 37° has been allowed to proceed for one hour, shows the presence (after treatment of the paper with aniline hydrogen phthalate) of two products. Their positions are identical with those taken by authentic samples of D-glucosamine-6-phosphate and of hexosediphosphate. Soodak[21] has reported that, in the degradation of N-acetylglucosamine by *E. coli*, fructose-6-phosphate is formed. It is possible that the hexosediphosphate formed in our experiments is produced secondarily by phosphorylation of fructose-6-phosphate by excess adenosine triphosphate present. Thus the evidence would indicate the existence of the following reaction sequence in an *E. coli* extract:

$$\text{D-glucosamine} \xrightarrow{\text{ATP}} \text{D-glucosamine-6-phosphate} \rightarrow$$

$$\text{fructose-6-phosphate} + \text{ammonia} \xrightarrow{\text{ATP}} \text{hexosediphosphate.}$$

Stimulatory effects of N-acetyl glucosamine with E. coli. A noteworthy feature of anaerobic D-glucosamine deamination by *E. coli* extracts is the stimulatory effect of small quantities of N-acetylglucosamine. Although N-acetylglucosamine is itself phosphorylated and deaminated by *E. coli*, its presence in low concentrations greatly increases the rate of D-glucosamine deamination. For example, the presence of 0·0005 *M* N-acetylglucosamine doubled the rate of disappearance of D-glucosamine in an *E. coli* extract containing 0·005 *M* D-glucosamine and 0·003 *M* adenosine triphosphate. Results of a typical experiment showing the stimulatory effect of N-acetylglucosamine on D-glucosamine deamination are given in Table 1.

Crude *E. coli* extracts deaminate D-glucosamine anaerobically so long as adenosine triphosphate and magnesium ions are present. Dialysed *E. coli* extracts bring about little or no anaerobic deamination of D-glucosamine in the presence of adenosine triphosphate and magnesium ions unless a small quantity of N-acetylglucosamine is added.

The stimulatory action of N-acetylglucosamine on D-glucosamine deamination cannot be brought about by such acetylated substances as N-acetylmethionine, acetylcholine or N-acetylglycine.

Inhibition of E. coli phosphatase by N-acetylglucosamine. The stimulatory action of N-acetylglucosamine may be due in part to the remarkable effect of this substance in inhibiting hexosemonophosphate breakdown in *E. coli* extracts. At concentrations of 0·001–0·002 *M*, N-acetylglucosamine will secure inhibitions of 50 per cent or more of hydrolytic breakdown of hexosemonophosphates. Typical results are shown in Table 2. Inhibitions of this order are not found with hexosediphosphate breakdown.

D-Glucosamine at 0·002 *M* shows no inhibition of glucose-1-phosphate hydrolysis with an *E. coli* extract under conditions where N-acetylglucosamine shows 94 per cent inhibition. Neither glucose nor

Table 2. EFFECTS OF N-ACETYLGLUCOSAMINE ON PHOSPHATASE ACTIVITY OF DIALYSED *E. coli* EXTRACT

Substrate (0 01 *M*)	Concentration of *N*-acetylglucosamine	Percentage inhibition of phosphatase
Glucose-1-phosphate	0 001 *M*	50
	0 002 *M*	76
	0 01 *M*	88
Glucose-6-phosphate	0 002 *M*	50
Fructose-6-phosphate	0 002 *M*	33
Hexosediphosphate	0 001 *M*	2

fructose is as effective an inhibitor of glucose-1-phosphate breakdown as N-acetylglucosamine.

In view of this phenomenon, it is suggested that the stimulatory or catalytic action of N-acetylglucosamine on anaerobic D-glucosamine deamination may be due in some measure to an inhibitory effect on the hydrolysis of a phosphate ester formed during the course of D-glucosamine breakdown. Conceivably, however, the phosphate ester of N-acetylglucosamine may play a part in the catalytic reaction.

Deamination of D*-glucosamine by brain extracts.* D-Glucosamine is deaminated anaerobically by a dialysed brain extract in the presence of adenosine triphosphate and magnesium ions. This process is not, however, stimulated by the addition of N-acetylglucosamine. It should be noted in this connexion that N-acetylglucosamine at 0·01 *M* has no inhibitory effect on animal phosphatases, for example, prostate acid phosphatase, intestinal alkaline phosphatase, kidney phosphatase. N-acetylglucosamine is not deaminated in brain extracts, nor does it undergo phosphorylation in the presence of adenosine triphosphate[1]. The presence of glucose inhibits anaerobic deamination of D-glucosamine in a brain extract, this probably being due to competition between glucose and glucosamine or between their respective esters.

The evidence would indicate that D-glucosamine-6-phosphate is the substrate of the anaerobic deaminating enzyme in brain tissue as in *E. coli*, but that the factors in *E. coli*, operating with N-acetylglucosamine and which account for the effects of this substance in the bacterial deaminating system, are not present in the brain extract.

We are indebted to the National Cancer Institute of Canada for a grant-in-aid.

FACTORS AFFECTING THE VERNAL PHYTOPLANKTON OUTBURST IN THE ENGLISH CHANNEL

By Dr. W. R. G. ATKINS, C.B.E., O.B.E.(Mil.), F.R.S.

Antony, Cornwall

AND

PAMELA G. JENKINS

Plymouth

WHEN in 1923[1] a systematic survey was begun of the seasonal variation in phosphate in the waters of the English Channel, it soon became clear that the time of the phytoplankton outburst, as indicated by phosphate consumption, might vary by eight or ten weeks[2].

The phosphate is at a maximum about the end of January. Thereafter increasing light intensity favours growth and cell multiplication, though vertical circulation, which brings cells down to badly lighted depths, slows the processes. Warming of the surface water progresses until a stable layer is maintained above a colder deep layer. Since the group of the phytoplankton which predominates in these waters—the diatoms—takes up silica for the valves, the changes in this were also ascertained[3].

The delays in the spring outburst were puzzling and not easily accounted for by any alteration in the seasonal increase in light, though, of course, the influence of vertical mixing is difficult to assess. It was suggested by Harvey[4] that some minor constituent of sea water might be lacking for growth. Sverdrup, Johnson and Fleming[5] also suggested that some conditioning of the water was necessary. It was then pointed out by Atkins[6] that this seemed unlikely as it was so early in the year, and complete regeneration of phosphate, and presumably of other constituents, had just occurred. Furthermore, a lag in phosphate consumption, well beyond that expected from the illumination, was a mathematical necessity. Only after repeated cell divisions could the phosphate consumption come within the limit detectable by our most sensitive methods. Once detectable, repeated doublings in consumption soon led to exhaustion.

There were, however, other questions behind this: How great had the winter reduction in the number of the diatoms been? Multiplication of a smaller stock required, of necessity, a longer period to become perceptible. There might be an inflow of a water mass with a lower population; but against this was a uniform phosphate content and a uniform salinity over an area in which meteorological conditions were reasonably constant. We finally approached the problem through the neglected study of the algal cells themselves[7]. Filtering water on collodion disks, we extracted with 80 per cent aqueous acetone and examined the clear liquid by spectrophotometer, measuring in the chlorophyll absorption bands. Volumes of the water were also placed in diffuse light, after enrichment with nutrient salts, and the development of many algal species was studied by repeated examination. In time we came across a year in which the low chlorophyll yield found in January was followed by a slightly lower yield in February. Even March was low. At first it seemed impossible. But phosphate determinations in 1925 [2] had indicated very similar late development. The routine phosphate and silicate determinations were at this period made by Armstrong[8] and, as always, the salinity by the Government Chemist's Laboratory. Neither temperature nor salinity suggested that the water mass at our station, *E*1, was in February or March different from what it had been in January. Both pointed to identity, as did also the phosphate, which even rose very slightly in February. But the silicate analyses were startling; from February on they were at a much lower level, having fallen from 4·70 to 2·83 μgm. atoms of silicon per litre. This, unaccompanied by a fall in phosphate, was clear proof that we had to deal with a different water mass, in which the chlorophyll values indicated a sparse plankton. The cultures, too, showed certain differences in the predominant species.

It thus appears that the lateness of the phytoplankton outburst was, in 1954 at least, due to a change in the water mass, which was undetectable by the usual criterion, salinity. This does not, however, demonstrate that mere changes in the vertical circulation may not, in other years, be of importance. We hope shortly to publish elsewhere the full account of such yearly changes.

ELECTROMAGNETIC PHENOMENA OF NATURAL ORIGIN IN THE 1·0-150 C./S. BAND

By DR. PHILIP A. GOLDBERG
Department of Physics, University of Oregon, Eugene, Oregon

ALTHOUGH electromagnetic activity of natural origin has been intensively studied in geomagnetic work, the frequencies involved usually have been no higher than 0·1 c./s. However, Willis[1] has reported the detection of magnetic noise fluctuation signals in the 5–800 c./s. band; and Aarons and Henissart[2] have reported observing signals with equipment of band-pass of 0·5–20 c./s.

To determine some of the characteristics of natural activity at low audio and sub-audio frequencies, the University of Oregon, with the assistance of the Research Corporation, has conducted a series of observations of geo-electromagnetic activity in the 1·0–150 c./s. band. The observations were carried out during the summer of 1955 at an isolated place in eastern Oregon (lat. 43° 27′ N., long. 120° 35′ W.) where no interference by power lines was observable.

For detecting signals, two air-core detector coils were used. One, of effective area 12,800 sq. m., was arranged to observe the vertical magnetic field component; the other, with an effective area of 5,500 sq. m., was arranged to observe the horizontal north–south component. The signals from the coils were amplified with an amplifier having a band-pass of 1·0–150 c./s. Coil voltage wave-forms, proportional to the time-rate of change of the magnetic field, were studied by mean of a photographically recording cathode-ray oscilloscope. Oscilloscope recordings depicting the wave-form of the inducing field itself were obtained with the aid of equalizing networks, adjusted so that the response of an entire observing system, including the detector coil, was proportional only to the instantaneous value of the field. Coil-voltage signal-level was continuously recorded by means of a rectifying, ink-recording milliammeter with linear response.

Activity in the low-frequency bands was found to be due to disturbances which are almost all of a predominantly burst-like form. Fig. 1, a photograph of an oscilloscope display of the wave-form of the

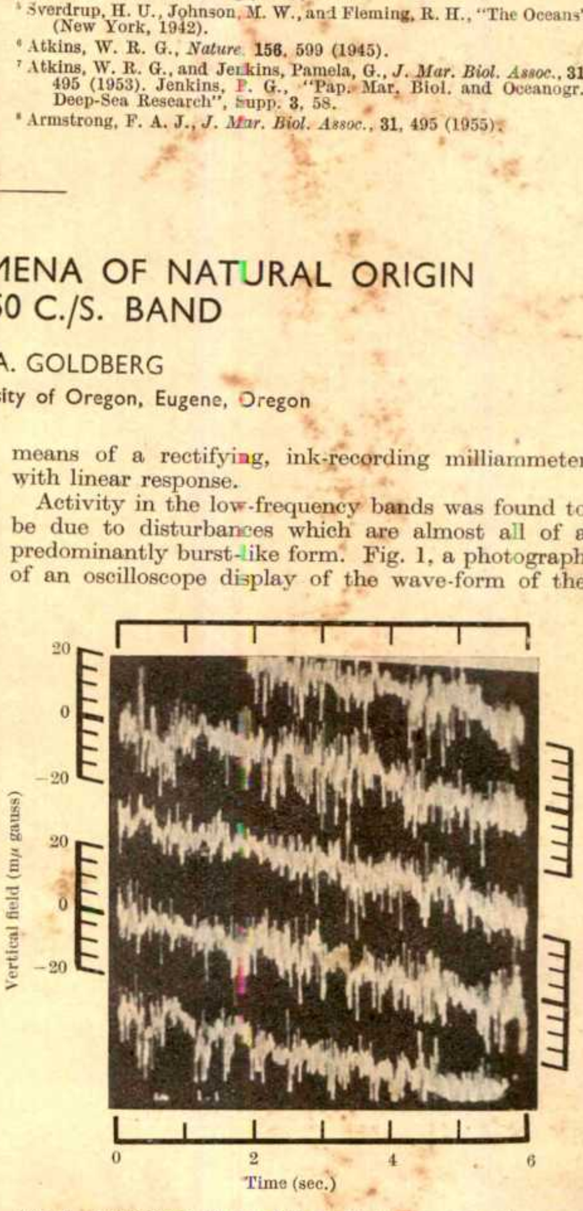

Fig. 1. Oscilloscope display of the vertical component of super low-frequency magnetic fluctuations, 16 : 34, Aug. 18, 1955, L.M.T. In the five-sweep raster, each sweep represents a time of 6 sec.

vertical fluctuating magnetic field, shows this principal feature of the activity in the 1–150 c./s. band. The magnitude of the vertical field bursts are of the order of 10^{-8} gauss. The rate of countable bursts is of the order of 20 bursts per second. Expanded scale-sweeps show the bursts to have durations ranging from 4 to 10 m.sec. (It should be noted that, in Fig. 1, long-period fluctuations, of duration greater than about 0·1 sec., are due to system noise, the low frequencies of which are emphasized by the equalizing network. Also, the broadening of the sweep base-line, when the inducing field is apparently quiescent, is due to small unresolved bursts.)

Both the north–south and vertical magnetic components of the activity are, so far as could be determined, similar as regards rate and duration of bursts. The north–south component is, however, much the stronger, having a magnitude of the order of 3×10^{-7} gauss.

Coil signal voltage, a typical wave-form of which is shown in Fig. 2, was used as a basis for continuous 24-hr. monitoring of the level of activity of burst disturbances. Coil voltages were amplified without equalization, full-wave rectified and then recorded on a recording milliammeter. The five-second response time of the recorder was sufficiently long to give an easily readable smoothed indication.

The level of the super low-frequency disturbance activity, recorded in this manner, varies considerably during a 24-hr. period, but in a highly systematic fashion. Fig. 3. which is a plot of quarter-hour values of rectified coil-signal voltages, due to north–south field activity, indicates the highly regular and diurnal nature of the variation of the activity.

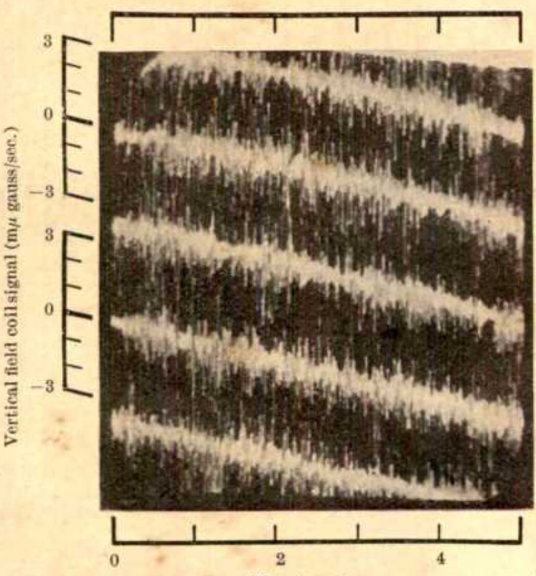

Fig. 2. Oscilloscope display of coil voltage wave-form due to vertical component of fluctuating magnetic field, 16 : 11, Aug. 19, 1955, L.M.T.

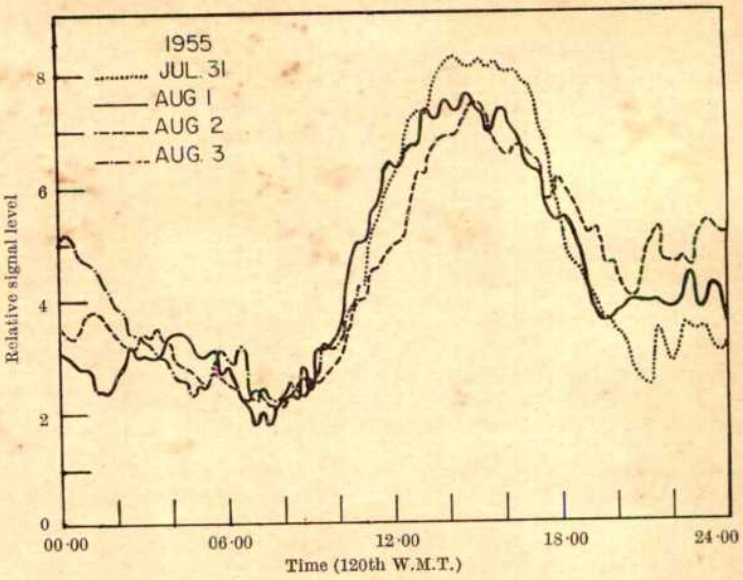

Fig. 3. Daily variation of coil signal-level due to north–south horizontal component of super low-frequency magnetic fluctuations

The 24-hr. variation of the signal level as observed with the vertical-component coil has a similar form, and for both components the level varies by a factor of about 4 during a typical day.

Analysis of some additional results confirms the regular and pronounced diurnal variation, although there are differences in minor details from day to day. However, the features of a principal minimum occurring at 0700 hr. L.M.T., a secondary minimum at 2100–2200 hr., a very strong major maximum at 1400–1600 hr., and a minor maximum at 2300–0100 hr., were always strongly present during the summer observations.

The burst character of the super low-frequency disturbances is suggestive of atmospherics such as are observed on the radio-frequency bands, and which are attributed to lightning activity. Simultaneous comparison with radio-frequency atmospherics at 500 kc./s. usually showed a correspondence; and so the super low-frequency activity is probably largely, if not entirely, due to lightning activity. However, the daytime maximum of super low-frequency activity as contrasted with the daytime minimum of medium radio-frequency atmospherics signals indicates that different features of propagation are involved.

The general form of the curve of Fig. 3 is taken to represent the manner in which the variation of sources of disturbance is modified by daily variations of the earth–ionosphere propagating system. Because of the extremely long wave-lengths characterizing the super low-frequency activity, it is the variations of the lowest level of the ionosphere which should be important in this connexion. An important feature of the curve in this regard is the regular morning minimum, which for the summer observations occurred at 0700 hr. L.M.T. The indication then is that for the daytime ionosphere the lowest level of ionization affecting super low-frequency propagation between points on the sunlit hemisphere begins to be effective about two hours after ground sunrise.

An Investigation of Monochromatic Radio Emission of Deuterium from the Galaxy

The possibility of monochromatic radio emission from galactic deuterium has been well known for some time, and the frequency of such an emission line predicted by Shklovsky[1]. The expected maximum intensity is such that any attempt to detect the line must rely on extremely long integrations in time. In practice, this requires either direct electrical integrations over a long period or the manual summation of a series of individual records. One attempt to detect the line using manual methods has already been published[2].

The radiometer used in our experiments was of a type used by van de Hulst, Muller and Oort[3]. One major difference was the use of a reactance tube switch rather than two oscillators. A filter bandwidth of 16 kc./s. was used, and the spacing between the filters was 48 kc./s. These parameters were derived from considerations based on the hydrogen line profiles in the direction of the galactic centre.

The receiver input stage was a simple crystal converter, which was used mainly for obtaining uniform sensitivity and maximum reliability. The single band noise factor of the receiver was measured at 6, and this noise factor also checked for uniformity over the frequency sweep. A commercial co-axial diode was used for checking the noise factor, and this instrument was in turn checked against laboratory receivers.

Frequency calibration of the second local oscillator (37 Mc./s.) was checked by an interpolation from a 2 and 5 Mc./s. crystal oscillator. These crystal units were in turn checked against *WWV*. The drift of this oscillator was found to be less than 1 kc./s. over a period of a month; consequently no check was kept on it during an observation, and calibration was limited to immediately before and after a record. The first local oscillator was set on 296 Mc./s. and a constant check was kept on the heterodyne beat note during an observation with the harmonic of a 2 Mc./s. crystal oscillator.

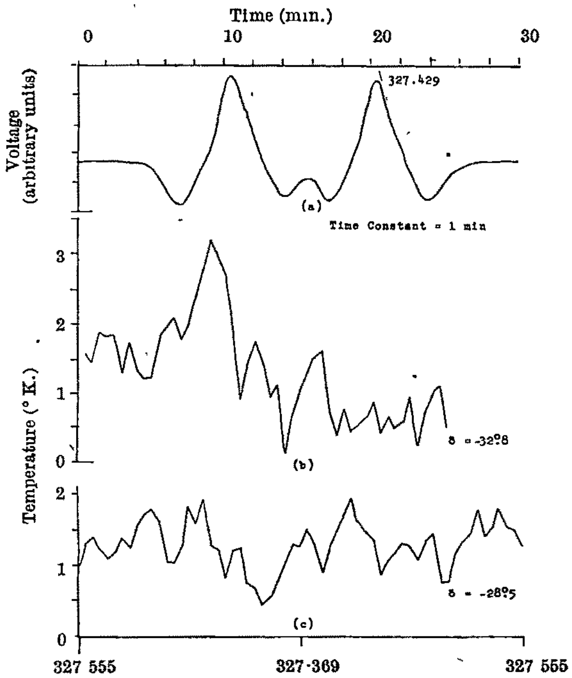

Fig. 1. Integration of five records

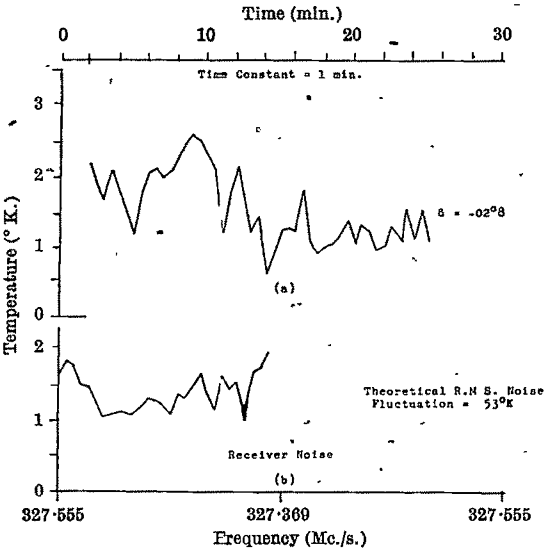

Fig. 2. Integration of eight records

The antenna system was a paraboloid of 80 ft. diameter, described by McGee, Slee and Stanley[4]. To maintain the frequency response as flat as possible, a cylindrical dipole was used as the primary feed. An overall calibration of the antenna system was difficult due to the limited angular movement of the beam. However, measurements of solar radiation, which were possible only near the summer solstice, were in good agreement with those made on the same day with other solar equipment. A relative check was set up at the same time, consisting of a known signal radiated from a dipole placed near the antenna.

Observations were limited to the region about the galactic centre and the region in the galactic plane at l — 220°. All observations were reduced to the local standard of rest.

Early observations were made by automatically scanning with the receiver through 200 kc./s. as the direction of the galaxy passed through the antenna. Such methods failed to detect any radiation. In the later records graphical integration was performed to increase the sensitivity.

A complete frequency scan occupied 15 min., and to compensate partially for the observation with a fixed antenna the phase of the frequency with respect to sidereal time was staggered on successive runs. The time constant of observing was 1 min. Fig. 1(*a*) shows the profile expected from a monochromatic line and Figs. 1(*b*) and (*c*) the results of five integrations at declinations — 32·5° and — 28°. Fig. 2 shows eight integrations at declination — 32·8°, together with a sample integration of noise alone for the same number of records.

As there was still some doubt about Fig. 2, a further series of four observations with a time-constant of 3·5 min. and a scan of 50 kc./s. was made at declination — 32·8°, and the results are given in Fig. 3.

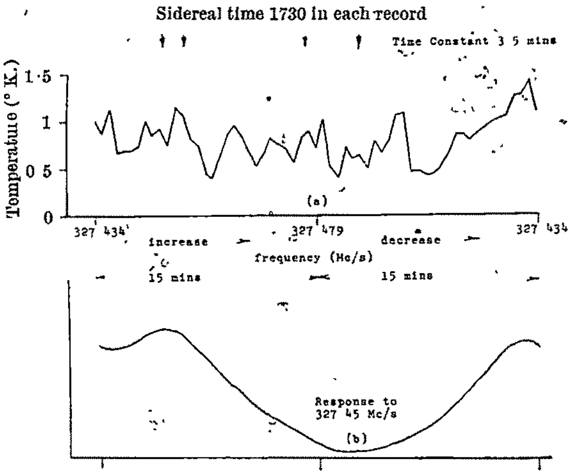

Fig 3. Integration of four records

We conclude that a monochromatic radiation from deuterium could not be detected at the galactic centre to a limit of better than 1° K. aerial temperature. Shklovsky has estimated that 1/500 of the aerial temperature of the continuous radio radiation from the galaxy at this frequency seen in absorption corresponds to a concentration of deuterium equal to 10^{-3} of the concentration of hydrogen in the galaxy. For the antenna used the aerial temperature of the central source is approximately 800° K. The abundance of deuterium should therefore be less than 10^{-3} that of hydrogen.

This work was carried out during 1954 at the Radiophysics Laboratory of the Commonwealth Scientific and Industrial Research Organization, Sydney, Australia.

A Simple Method of studying Winds in the Ionosphere by using Continuous-wave Radio

Systematic study of horizontal movements in the ionosphere has been made during the past few years by using the spaced-transmitter technique developed by Munro[1], which is applicable only for the F_2 region, and the spaced-receiver method first employed by Mitra[2]. However, both these methods require elaborate and expensive ionospheric pulse-sounding equipment. We present here a simple method of studying winds in the ionosphere using continuous-wave transmissions and a simple receiver with a recording system.

The method is essentially similar in principle to the spaced-receiver pulse technique and involves the use of continuous-wave transmissions from a distant short-wave transmitter arriving at the receiving site by way of single reflexion from the ionosphere. Simultaneous records of the variations of signal strength at three spaced points due to these transmissions showed fading patterns which are almost identical but displaced in time. The wind velocities and directions are then estimated from these time displacements using a method of calculation similar to that in the spaced-receiver pulse method.

Continuous-wave transmissions from Madras on the 31-metre band have been used in this investigation for obtaining the simultaneous records of variation of signal strength at the spaced-receiver points. Three simple vertical aerials R_1, R_2 and R_3 each of length 8 ft. are placed at the corners of a right-angled triangle such that R_1 and R_2 and R_1 and R_3 are along the north–south and east–west directions with separations of 64 and 60 metres respectively. The signals induced in all these aerials are brought to a central recording station by using coaxial shielded cable. In the earlier part of this investigation we used three galvanometers which are suitably damped, and three communication receivers connected to these aerials, for obtaining the simultaneous record of the variations of signal strength. Light spots reflected from these three galvanometers trace out the variations of signal strength side by side on the same photographic paper moving with a speed of 12 in. per min. The photographic paper is rolled on a special drum recording-camera driven by a synchronous motor at the rate of one revolution per min. With the view of eliminating the variations, if any, in the signal-strength records for all the aerials, we afterwards simplified the technique still further by using only one communication receiver, National *HR* 07, and a specially designed two-pole three-way rotary switch driven at 1,420 r.p.m. by a 1/8 h.p. motor. The switch consists of two sections each of which has a rotating vane moving over three insulated brass contacts of equal length arranged in a circle. The input and automatic volume control terminals of the receiver are connected to the movable vanes of the two sections of the rotatory switch in such a way that during the rotation each galvanometer is connected to the amplified signal from one of the aerials only during one-third of the rotation. The rate of rotation of the movable vane of the switch being quite high, a smooth fading record is obtained though it is an interrupted signal that is fed to each galvanometer.

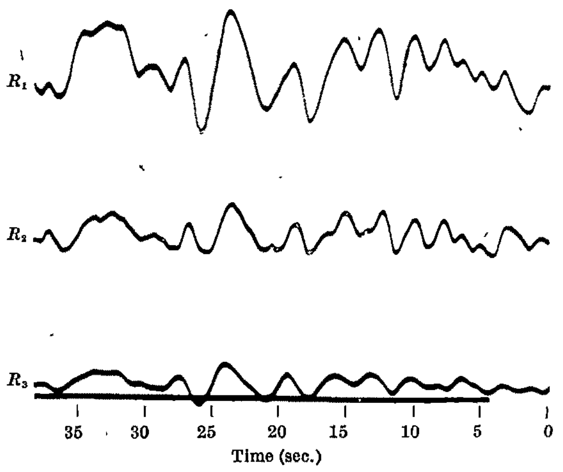

Fig. 1

A typical record obtained with this arrangement on October 30, 1955, from 0900 hr. is shown in Fig. 1. It can be clearly seen that the pattern is almost identical in all the three records with a slight time displacement. From the known data of the critical frequencies and the maximum usable frequency factor it was inferred that the reflexion is from the F_2-region of the ionosphere. The wind velocities and directions in the F_2 region are then determined from these time differences, which are attributed to the horizontal drift of the diffraction pattern on the ground produced by irregularities in the ionosphere. Results obtained for wind velocities in the F_2 layer are found to be in the range 40–90 metre/sec., the direction of wind movement being predominantly in the range of 150°–230° east of north. These observations are in agreement with the values obtained by us using the spaced-receiver pulse technique. We have also tested the reliability of this method by determining the wind velocities and directions from records taken almost simultaneously using the transmissions on the 31-metre band from Calcutta and Madras which are situated to the north and south of Waltair. The values thus obtained for both the records agree very well.

The method has the unique advantage of simplicity of technique, because no pulse transmitter and the associated trigger circuits and oscillographs required for the spaced-receiver pulse method are needed. The only disadvantage is that the transmission must be so chosen that fast magneto-ionic fading and periodic fading due to multiple reflexions are not present. We have chosen the times of observations and the frequencies of transmissions such that only the single-hop reflexion from one layer is prominent.

A detailed report of these investigations will shortly be published elsewhere. We thank the Radio Research Board for sponsoring this research scheme, and the Council of Scientific and Industrial Research for financial assistance.

Sudden Decrease in Low-frequency Atmospheric Noise during the Cosmic-Radiation Storm of February 23

At Churchill, Manitoba (lat. 58·8° N., long. 94·2° W.), an unusual event occurred on the 100-kc./s. atmospheric noise recordings on the morning of February 23. Churchill is situated near the region of maximum intensity of the auroral zone.

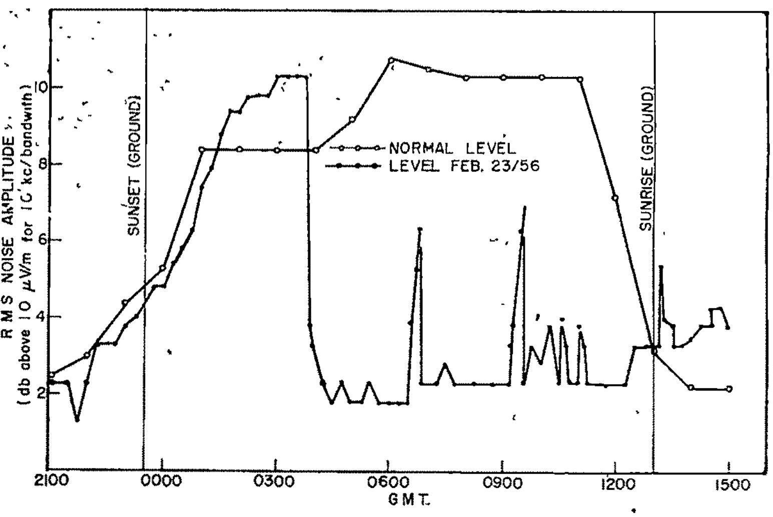

Fig. 1 Atmospheric noise at Churchill, Manitoba

In Fig. 1 two graphs of the root-mean-square atmospheric noise amplitude (decibel above 1·0 µV./m. for a 1-kc./s. band-width) versus time (G.M.T.) are plotted, from 2100 hr. February 22 to 1500 hr. February 23. One of the curves shows the normal variation of noise at Churchill for this particular time of year. The other curve shows a sudden decrease of atmospherics beginning at 0345 G.M.T. on February 23.

This decrease of atmospherics is the first of its kind to be recorded in Canada at a high-latitude station. The largest part of this decrease is a drop in noise amplitude of 6 db. in less than 10 min. The noise continued to fall another 2 db. in the next half-hour to its normal day-time level. The noise continued at this day-time level except for a few short bursts until the early hours of February 24 when the noise-level increased 3–4 db. The atmospheric noise-level did not return to its full normal condition until February 27.

During this same period, in the sunlit half of the hemisphere, Tokyo reported a large solar flare of 'Importance 3', beginning at 0334 and ending at 0414 G.M.T. The time of maximum intensity of this flare was not recorded. During this same period and coinciding in time with the decrease of noise at Churchill, the National Bureau of Standards, Colorado, reported an exceedingly large increase in cosmic-ray activity beginning at 0345 G.M.T.

During the winter months, the nearest sources of atmospheric noise to Churchill are Central America and the northern part of South America. At the time of this sudden fadeout, propagation from these sources was entirely through the dark half of the hemisphere, which makes this particular record unique and, as such, it cannot be termed a normal S.I.D.

The vertical-incidence sweep-frequency ionospheric recorder at Churchill, operating the range of frequencies 0·6–20 Mc./s., did not show signs of increased absorption until 1 hr. later. At 0445 G.M.T. the minimum frequency of $f0F2$ began to increase until 0530 hr., when a total blackout condition existed. During the next 65 hr. a total of 53 hr. of full blackout was recorded. Farther north at Baker Lake (lat. 64·3° N., long. 96·0° W.), the ionospheric recorder did not show blackout condition until 0600 hr. G.M.T., which is one half-hour later than the commencement of the blackout at Churchill. For the same 65-hr.

period a total of 47 hr. of total blackout was tabulated. The more southerly stations, Winnipeg (lat. 49·9° N., long. 97·4° W.) and Ottawa (lat. 45·4° N., long. 75·9° W.), did not show any immediate effect of the ionospheric storm except for a high degree of absorption at the minimum frequency of *f0E* and an unusual amount of sporadic *E* during the daylight period of February 23. The ionospheric tabulations from Kjeller, Norway, which is in approximately the same geomagnetic latitude as Winnipeg, Canada, show that the storm there began near 0500 G.M.T., which is the same time as at Churchill, Canada. However, it was much less severe, with only two hours of total blackout condition at 0700 and 0800 hr. G.M.T.

For this solar flare there appeared to be a sudden increase in the *D*-region absorption on the darkened half of the hemisphere which cannot be attributed to ultra-violet radiation. It also appears that this condition may occur only at high latitudes situated near the auroral zone.

Termination of Chains in Vinyl Polymerization by Metal Salts

In a recent communication, Bamford, Jenkins and Johnston[1] have stated that ferric chloride dissolved in non-aqueous solvents is reduced by polymer radicals according to the equation:

$$m_j + \text{Fe(III)} \xrightarrow{k'_t} P_j + \text{Fe(II)} \qquad (1)$$

and that in certain circumstances the rate of formation of divalent iron can be identified with the rate of initiation of polymerization. Our purpose is to report very briefly some recent results obtained in these laboratories, some of which have already been published[2], which (*a*) indicate that the oxidation and reduction of organic radicals by metallic salts is a general phenomenon which can take place in a variety of media, (*b*) confirm that the rate of the reaction depends on the polymeric radical, (*c*) show that the rate depends on the nature of the metal ion, (*d*) show that in a polymerization system in which the probability of chain transfer is low this reaction can be used for determining the number average degree of polymerization, and (*e*) demonstrate that reaction (1) is useful in studying post-irradiation effects.

As regards (*a*) and (*c*), we have pointed out elsewhere[2] that polyacrylamide radicals dissolved in water will reduce the following ions: Fe^{3+}_{aq}, $\text{Fe}^{3+}\text{OH}^-$, and Cu^{++}. We have recently measured the velocity constants for some of these reactions, and the values at 25° C. for the first two of these ions are $2 \cdot 2 \times 10^{-3}$ and $1 \cdot 4 \times 10^4$ l.mole^{-1} sec.$^{-1}$ respectively[3]. There is evidence that radicals derived from some simple organic molecules such as alcohols and aldehydes by the attack of hydroxyl radicals will reduce ferric ions, whereas those from acetone or acetic acid oxidize ferrous ions[4], and phenyl radicals appear to be capable of either reaction[5], in aqueous solutions. The study of the X- and γ-ray irradiation of de-aerated dry alcoholic solutions of ferric chloride demonstrates the great ease with which this solute is reduced by organic free radicals in this medium[6].

In discussions of the mechanism of these reactions[7], we have emphasized that the lower the ionization potential of the reducing ion the more likely is the organic radical to be reduced, and have cited in support of this the capacity of chromous ions to reduce polyacrylonitrile radicals in water[8]. The hypovanadous (V^{2+}), vanadous (V^{3+}), molybdenous (Mo^{3+}), titanous (Ti^{3+}), uranous (U^{3+}) and azide ions react in a similar way[9]. It has also been pointed out that the reactivities of organic free radicals towards inorganic ions depend on the oxidation-reduction potentials for the processes $R \rightarrow R^+ + e$ ($E_{(-e)}$), and $R + e \rightarrow R^-$ ($E_{(+e)}$)[10].

Recently, we have been re-investigating the behaviour of various polymer radicals in water and now find that, whereas polyacrylonitrile radicals and polyacrylamide radicals will reduce ferric perchlorate, polymethyl methacrylate radicals react only slowly if at all[11]. The implication is that the oxidation potentials, $E_{(-e)}$, of the radicals from acrylonitrile and acrylamide are less positive (on the European scale), while the potential $E_{(+e)}$ of the radical from methyl methacrylate is more positive, than the potential of the ferrous/ferric system under the conditions obtaining.

When the rate of polymerization is proportional to the monomer concentration and the radiation intensity (with ultra-violet light or ionizing radiation) and is inversely proportional to the weighted sum of the concentrations of the ferric species present, the rates of initiation and termination of the chains are equal to the rate of formation of ferrous species in the latter reaction. This relation may be used in two ways. First, the rate of chain initiation can be evaluated in the manner described by Bamford *et al.*[1] and by us[2,3]. Secondly, when the transfer constants are so negligible that the kinetic chain-length is equal to the number average degree of polymerization ($\overline{DP}$) we may write:

$$\overline{DP} = R_p \bigg/ \frac{\text{d Fe(II)}}{\text{d}t} \qquad (2)$$

and $\overline{DP}$ may be found directly from the measured rates of polymerization and of ferrous ion formation. This is the state of affairs referred to in (*d*) above, and it obtains when acrylamide is polymerized in aqueous solutions containing ferric salts, the polymerization being initiated with light of wave-length 3130 A., X-rays or γ-rays[2,3]. In these systems there is no detectable transfer to the solvent, the ratio of the monomer-transfer constant to the propagation constant[3] is 10^{-5} and the ferric ion present restricts the value of $\overline{DP}$ to $< 10^4$.

In both the catalysed and the radiation-initiated polymerization of acrylamide and acrylonitrile in aqueous solutions, certain long-lived after-effects are observed, the origin of which does not concern us here[3,11]. In the study of these effects it is important to know the rate of initiation, and this may be found quite simply by measuring the rate of ferrous ion formation in systems containing sufficient ferric salt to ensure that chain termination is exclusively by reaction (1). The values of the rates of initiation so obtained agree with those calculated from other properties of the after-effect[3].

Change of Hardness in Steel due to Hydrogen

A change in the hardness value of a steel due to the presence of diffusible hydrogen has been detected and found to be in agreement with that predicted from the change in the work-hardening characteristics of the particular steel. This change in hardness has not previously been observed[1–3].

Maximum embrittlement of a steel containing a given amount of hydrogen has been shown by numerous investigators to be dependent on the rate of strain and the temperature of tensile testing. These factors indicate dependence on diffusion. It follows, therefore, that the rate of loading of the indentor in hardness tests must also be critical. A slow-loading hardness test has been devised and has shown changes of hardness dependent on the hydrogen content of the steel.

Specimens were prepared from a wrought, low-carbon (0·17 per cent) mild steel. Hydrogen was introduced cathodically using a 10 per cent aqueous solution of sulphuric acid containing a trace of arsenious oxide and a current density of 0·2 amp. per sq. in. Hardness tests were carried out at room temperature using a ball indentor of 1-mm. diameter and a load of 10 kgm. An oil dashpot device in the hardness tester was adjusted so that the time taken to form the indentation was 60 sec., the load being applied for a further 15 sec. The hardness tests were carried out at fixed intervals of time after charging, the loss of hydrogen with time having been previously determined for similar conditions. The results of the initial tests made immediately after charging, together with conventional hardness determinations, are as shown in Table 1. A plot of the change of hardness with time and hydrogen content is shown in Fig. 1.

Table 1

Method of test	Diam. of ball indentor	Load (kgm.)	B.H.N. of as-received steel		B.H.N. of hydrogen-charged steel		Difference
			Range	Av.	Range	Av.	
Normal	2 mm.	120	116–118	117	115–119	117	—
Slow loading	1 mm.	10	108–111	110	123–130	127	17

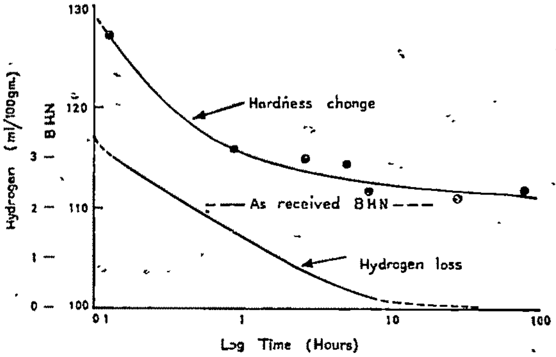

Fig. 1. Decrease in hardness and loss of hydrogen with time

The results show that an increase of 17 B.H.N. was obtained after hydrogen-charging, and that a reversion to the normal hardness values occurred after sufficient time has elapsed for the hydrogen to diffuse from the steel. This change in hardness compares favourably with the increase in slope of the work-hardening part of the stress–strain curve as predicted by Seabrook *et al.*[1] and shown by Vaughan and de Morton[4]. The use of high current densities for cathodic charging produces surface blisters and permanent surface cold-work resulting in a permanent increase in hardness which tends to obscure the above effect.

It would appear from these tests that hydrogen does increase the work-hardening characteristics of mild steel, presumably by the inhibition of slip. A theory relating to embrittlement by the locking of dislocations by hydrogen atmospheres is envisaged and a detailed account will appear elsewhere[4].

It is thought that slow-load hardness testing may be of value in investigating strain ageing phenomena in other systems, provided loading-rate and temperature are adjusted to conform to the rate of diffusion of the solute elements under consideration.

Separation of Hydrocarbon Isomers by Thermal Diffusion

Recent work on the transport properties of gaseous hydrocarbons[1] has suggested that highly flexible molecules undergo 'wrestling' intermolecular collisions, involving less persistence of forward velocity than collisions between other molecules. Since a straight-chain paraffin molecule is always more flexible than a branched chain, this effect gives rise to differences in the transport phenomena shown by isomeric hydrocarbons. Such differences might be expected to enable separation of a mixture of isomers by thermal diffusion. One view of the mechanism of separation by thermal diffusion is that those molecules which move faster when leaving the hot zone push the slower molecules towards the cold zone[2]. It is, in any event, clear that thermal diffusion must depend, not only on the mass and diameter of the molecules, but also on the nature of the intermolecular collisions. If a mixture of an *n*-paraffin with a branched-chain isomer is subjected to thermal diffusion, the former, which is the more flexible, will leave the hot zone with lower forward velocity, and would thus be expected to concentrate in the cold zone.

Experiments have been made on thermal diffusion in mixtures of *n*-pentane with *neo*-pentane, and show that a striking degree of separation occurs. Mixtures were admitted to a Clusius column, 1 metre long, consisting of concentric 'Pyrex' glass tubes. The inner tube, of outer diameter 8 mm., was heated to approximately 300° C. by an internal electrical heating element; the outer tube, of inside diameter 16 mm., was cooled by a water jacket at room temperature. The top of the column ended in a 2-litre reservoir; the bottom was connected by capillary tubing to a 20-ml. gas pipette. Samples were taken in the pipette both before running the column and after equilibrium had been attained, and were analysed by mass spectrometer. Equilibrium was reached within four hours. The results are shown in Table 1. The separation factor appears to be sensibly constant over the whole range of concentrations.

Table 1

Total pressure in column (mm. mercury)	Percentage of *n*-pentane: in initial mixture	Percentage of *n*-pentane: at bottom of column after separation	Separation factor*
225	43	60	2·04
175	43	64	2·44
175	11	21	2·31
175	91	96	2·37

$$* \text{ ratio}: \frac{\%\ n\text{-pentane at bottom}/\%\ neo\text{-pentane at bottom}}{\%\ n\text{-pentane at top}/\%\ neo\text{-pentane at top}}$$

Experiments are being continued with other mixtures of isomeric hydrocarbons, and full details will be published elsewhere.

Emission of Photo Radiations by the Impact of Positive Ions of Helium on Nickel

The emission of secondary electrons from metals by positive ions has been studied by a number of workers[1], and it has been established that the efficiency of this process depends upon the work function of the metal, the ionization potential of the ion and their kinetic energy. It is believed that a positive ion becomes neutralized before it actually comes into contact with the metal by extracting an electron from it and is in the excited state when it enters its surface. The energy of excitation of the atom is handed over to another free electron of the metal as it settles down to its ground-state in a radiationless process[2]. This electron escapes from the metal as a secondary emission.

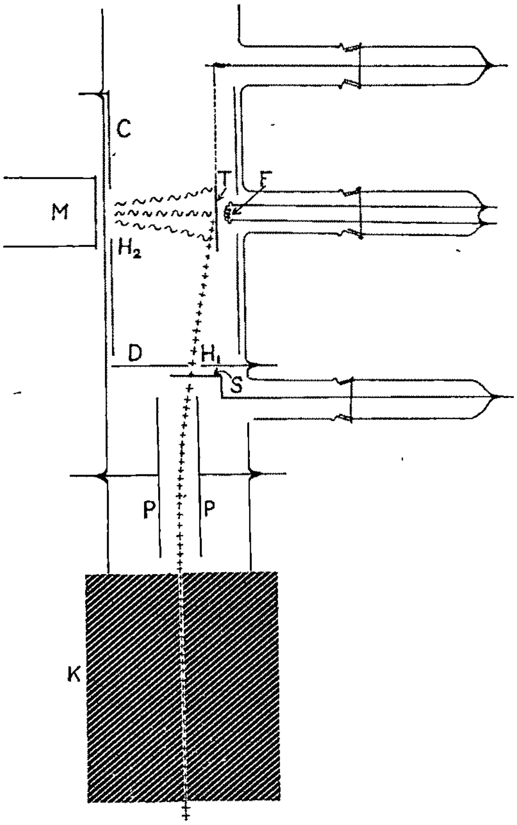

Fig. 1

We have carried out experiments with helium ions to see if their excited atoms formed in the manner described above would undergo transition to the normal state by emitting photo radiations on impact with a nickel surface.

A well-defined beam of ions is obtained from a discharge tube and is allowed to pass between two parallel metal plates *P* in an analysing chamber in which a high vacuum is maintained (Fig. 1). A little beyond these plates is placed a selector disk *D* with an eccentric circular hole H_1. By applying a suitable potential between the plates, the ion beam is deflected to pass through this hole and is made to strike the nickel target *T*, which is suspended from a ground-glass joint in a long nickel cylinder *C* with its lower open end resting just above the disk *D*.

The radiations from the target reach a photoelectron multiplier *M* through a circular hole H_2 made in the cylinder opposite *T*. The flow of ions to the target is stopped, when desired, by an adjustable nickel plate *S* without disturbing the discharge or any other condition of the experiment. The target was made of a degassed nickel sheet supplied by Messrs. Johnson Matthey and Co., Ltd., of London. It was further degassed by the filament *F*.

The pressure in the analyser was kept below 10^{-3} mm. mercury by two fast oil-diffusion pumps working in parallel and backed by a rotary oil pump. Two liquid-air traps, one between the analyser and the pumps and the other between the gas reservoir and the discharge tube, were used for condensing the impurities and preventing them from reaching the systems.

It has been observed that positive ions of helium give out photo radiations on impact on nickel surface. The energy of the ions used was 200–2,500 volts. That the photo radiations resulted from the impact of ions on the nickel target was verified: (1) by reversing the electrostatic field between the plates P, which deflected the positive ion beam in the reverse direction, and (2) by bringing the nickel plate S in front of the hole H_1 in the selector disk D to cut off the ion beam from the target.

Precautions were taken to ensure that light from the discharge tube or any other part of the apparatus did not affect the photomultiplier.

The apparatus was made of 'Hysil' or 'Pyrex' glass and was washed with helium before observations were taken. The discharge was passed in a cylindrical 'Pyrex' glass tube with a circular nickel disk as anode. The cathode K was made of brass and a hole 1·5 mm. in diameter was drilled along its axis and was water-cooled during the experiments. Spectroscopically pure helium, supplied by the British Oxygen and Acetylene Co., London, was fed into the discharge tube through a fine glass capillary leak from a reservoir maintained at a constant pressure.

Details of the experiments will be published elsewhere. Our thanks are due to Prof. M. L. Oliphant for his interest in these experiments.

Viscosity of Liquids and Ultrasonic Studies

THE Debye–Sears diffraction fringes of light, produced by ultrasonic waves from a generator, in the ordinary organic liquids are generally about the same in number. In strong contrast to this, it is found that the number of spectral orders observed in viscous liquids like castor oil, olive oil, etc., are appreciably smaller in number for the same electrical set-up.

To check up experimentally that the electrical condition remained unchanged in these two types of liquids, the oscillator was tuned to a non-resonant frequency of the quartz, midway between the fundamental and the third harmonic, so that vibrations were not set up. The quartz behaved as an additional condenser of the oscillating circuit only. It was noted from measurements that the electric power radiated, and thus, also, the oscillatory electric power of the circuit, remained approximately the same for the different types of liquids. This means that there has been no electrical effect produced by the change of liquids.

On the other hand, according to Raman and Nagendra Nath's theory[1], which has been verified experimentally, the smaller number of spectral orders in some liquids, as compared to others, indicates a smaller change in the refractive index of these liquids produced by the ultrasonic waves. The theory, primarily intended to give the variation of intensity in spectral orders, has been shown by Sanders[2] as well as by Samal and others[3] to give an approximately linear relation between the observed order number and the maximum change of refractive index of the liquids, particularly for order numbers higher than the third.

The experimental results for the set of liquids, on which observations have been made with a particular oscillator generating ultrasonic waves of 3 Mc./sec. frequency, within a distance of 1 cm. from the quartz, are recorded in Table 1. In noting the number of spectral orders, we have observed that in many of the liquids a definite number cannot be set with certainty. It often happens that a lower number appears with certainty and the higher number occasionally sets in. This indicates that the maximum variation of refractive index $\Delta\mu$ has an intermediate value between that required to produce the lower or the higher number of fringes. Under such conditions of observation, we have indicated the number of fringes by the two limits.

It will be observed that the values of $\Delta\mu$ decrease rapidly with the viscosity of the liquid. That the decrease in $\Delta\mu$ in any particular liquid is not caused by the strong absorption in the liquid can be seen by calculating the expected amplitude of change of pressure due to absorption. Since Δp is equal to $V^2.\Delta\rho$ and V, the velocity of sound, is constant in a liquid; also since $\Delta\rho$ is proportional to $\Delta\mu$, any change in amplitude of the pressure will give rise to a corresponding change in $\Delta\mu$ for a liquid. One may thus find that, except in the case of castor oil, where the corrected value of $\Delta\mu$, or n, would increase by one-third of its observed value, the other liquids will suffer negligible change for the experimental distance. The value of $\Delta\mu$ for castor oil, recorded in Table 1, is corrected for absorption.

Table 1. ULTRASONIC SPECTRAL NUMBER IN RELATION TO OTHER LIQUID PROPERTIES, AT 35° C.

Liquid	Density ρ	Velocity in m./sec. (V)	Compressibility.	Viscosity (η)	Spectral order $n = \varkappa \, . \, \Delta\mu$
Castor oil	0·957	1,460	49·0	3·16	3–4
Paraffin oil	0·876	1,393	58·8	0·765	5–6
Olive oil	0·911	1,398	56·2	0·465	6–7
Coconut oil	0·918	1,365	58·5	0·126	8–9
Turpentine oil	0·871	1,285	69·5	0·012	11–12
Toluene	0·851	1,263	73·6	0·005	13

It will be seen that the results can be incorporated into a fairly smooth relationship between $\Delta\mu$ and η, in the form $\eta = A \exp(-B\Delta\mu)$. No smooth relation occurs between $\Delta\mu$ and compressibility, which might have been the other possibility. The question regarding the decrease of $\Delta\mu$ with increasing η has to be critically considered. The decrease of $\Delta\mu$ could have been caused by the decrease of the amplitude of vibration of the quartz, due to the resisting viscous medium, or it could have been caused by the viscosity effect in the medium, without any change on the vibrating quartz. The effect of viscosity on the propagation of pressure amplitude in the form of absorption has been already considered. No other effect is likely on theoretical grounds. We are thus obliged to accept the view that the decrease of $\Delta\mu$ is due to the damping of the quartz by the viscous liquids.

This would mean that the different media would damp the vibrations of the quartz differently, by a resistance or opposing pressure π, inherent as a characteristic of the liquid. The damping of vibration and π would be larger the larger the viscosity. This also explains the observed fall of power in castor oil, previously recorded in the work of one of us[4]. The observed values of $\Delta\mu$ would thus decrease with the increasing values of π. Thus the relation between $\Delta\mu$ and π for a small range can be represented by $\Delta\mu = a - b\pi$. This would transform the viscosity relation into the form, $\eta = \alpha \exp(\beta\pi)$. It is premature at this stage to make critical observations on α and β, which, within the conditions of experimental limitations, appear to be constants.

It may, however, be noted that Frenkel[5], from considerations of the kinetic theory of liquids, obtained the viscosity relation in the form $\eta = A \exp(\beta p)$, where p is the external pressure and η gives the viscosity of a particular liquid. It appears that the external pressure increases the stiffness of the liquid, measured in terms of π, and so increases the viscosity of the liquid.

Indentation Hardness of Diamond

RECENTLY, S. Tolansky and V. R. Howes[1] published some data on indentation compression strength with a diamond ball (0·39 mm. radius) on differently orientated diamond faces. They obtained values for the pressure which caused cracking on different diamond faces ranging from 1·2 to $1·8 \times 10^{11}$ dyne-cm.$^{-2}$ (1,200–1,800 kgm./mm.^{2}). By comparing these values with those quoted in the literature it appears that they are extremely low: F. Auerbach[2], absolute hardness of diamond 2,200 kgm./mm.^{2}; Knoop, hardness[3] of diamond 6,500–8,500 kgm./mm.^{2}; Russian tests with triangular pyramids[4] and my own tests[5] with the same type of indenter indicated hardnesses greater than 14,000 kgm./mm.^{2}. Recent tests with double cone indenters (radius 2 mm., included angle 154°) showed that diamond surfaces could be loaded to well over 3,000 kgm./mm.^{2} without showing any form of cracks even when investigated with the electron microscope (by courtesy of Mr. M. Seal, Cambridge).

It is astonishing that these high average pressures, usually called hardness, should behave so differently with diamond surfaces. An explanation of this phenomenon may be given by the Hertzian formulæ[6] for the maximum pressure $p_{\max}$ between the surfaces.

The values of the average pressure and of the maximum pressure are shown in a histogram (Fig. 1) for a number of tests with various indenters. The average pressures with triangular and elongated pyramids are high, but with spheres and double cones relatively low. However, the relative stress factor was based on the highest maximum pressure $p_{\max.}$ obtained with triangular pyramids, and made equal to 13,000 kgm./mm.^{2}, which is the average of the average pressures for tests a, b and c. For test e we obtain a value of 6,350 kgm./mm.^{2}, which is close to the experimental value. For test f the value 1,350 kgm./mm.^{2} is about half the experimental pressure; but here no plastic deformation or any kind of fracture was observed. In contrast to this, in test g where elastic deformation was always followed by fracture, the maximum pressure is almost 50 per cent higher than the maximum average value recorded; this obviously indicates that the elastic limit has been well exceeded.

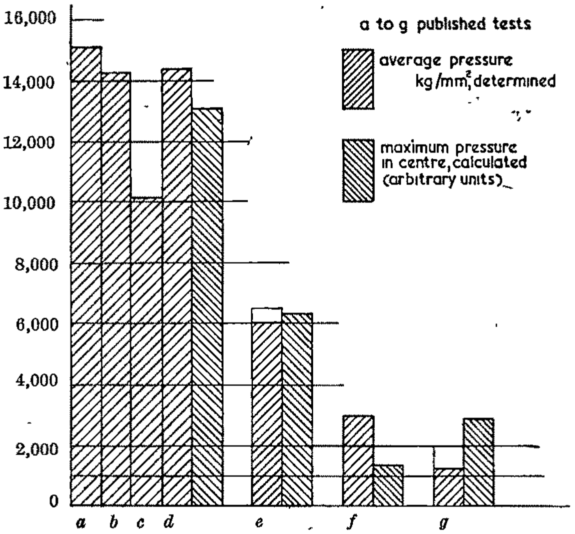

Fig. 1. Histogram of experimental values comparing average with maximum pressures.
a–c, M. M. Khrushchov and E. S. Berkovich (triangular pyramid). *d*, P. Grodzinski and W. Stein (triangular pyramid). *e*, Nat. Bur. Standards (Knoop elongated pyramid). *f*, P. Grodzinski (double cone, $r = 2$ mm., $a = 77°$). *g*, V. R. Howes and S. Tolansky (sphere, $r = 0·39$ mm.)

In this way the widely differing values of average pressures in kgm./mm.^{2} of diamond indenters against diamond surfaces can be explained. Obviously, different mechanisms are involved. In the tests with a pointed indenter (triangular and square base pyramids), there is plastic flow at shear stresses, whereas with tests with the double cone and spheres mainly elastic deformations occur up to the moment of fracture, the latter being due to tensile stresses. Therefore the average stress usually designated as hardness has no physical significance without knowing the shape of the indenter and the load. It may also be suggested that this applies to the usual hardness of materials of lower hardness than diamond.

A more detailed account of this work will be published elsewhere. I thank Mrs. A. Hoselitz for carrying out the tests with the double-cone diamond and Prof. S. Tolansky and V. R. Howes for useful comments.

A New Apparatus for Cathodic Sputtering

The cathodic sputtering process has been almost completely replaced in recent years by the vacuum evaporation technique for the production of thin solid films. However, renewed interest in the sputtering technique has been created by the discovery that films of metal oxide can be deposited by sputtering from a metal cathode in a glow discharge containing oxygen. Such films are usually required in combination with metal and other dielectric films for interferometry, etc. It is a simple procedure to deposit multi-layer coatings by vacuum evaporation, whereas their preparation is tedious when using the conventional form of sputtering apparatus. This is because it is necessary to break the vacuum and insert a new disk cathode of the required metal for each fresh layer. I have recently developed apparatus for the deposition during one coating cycle, on to plane receivers, of several sputtered films in sequence or for laminating sputtered deposits with vacuum-evaporated films. It is also possible to dispense with the need for rectification of the high-tension output without loss in the sputtering efficiency.

The new sputtering apparatus is shown in Fig. 1 (subject of a patent specification). The glow-discharge electrodes consist of two V-shaped elements made of the material to be sputtered and connected to the output of a high-voltage transformer. The leakage current from the supply to earth must be a minimum, otherwise sputtering can occur from earthed metal fittings in the chamber. Each of the V-electrodes operates as a cathode electrode on alternate cycles and deposits material on the plane receiver, which is rotated to ensure uniform deposition. The V-electrodes are mounted on earthed V-shaped shields with a gap of smaller dimension than the depth of the cathode dark space, so that a glow discharge cannot be sustained on the electrode side remote from the receiver surface. A V-shaped electrode operated from a d.c. supply has been used in Germany for glow-discharge cleaning prior to vacuum evaporation[1]; but it has not to my knowledge been used in the a.c. form described above for sputtering.

Experiments have shown that V-electrodes with arcs subtending an angle from 10° to 180° at the centre of the work plane produce very uniform deposits on a 12-in. diameter receiver when connected to a 3 kV. 500 m.amp. a.c. supply. By shaping the electrodes, it is possible to increase or decrease the thickness of the deposit at the centre of the receiver. The angular gap between electrodes must be such that one electrode does not penetrate the cathode dark space of the other and thereby interfere with the current density distribution over the cathode surface. This can be avoided by mounting the pair of V-electrodes diametrically opposite as in Fig. 1. Several such pairs of electrodes can be mounted above a rotary receiver for deposition of films in sequence.

To obtain uniform evaporated films on plane receivers, it is desirable to rotate the receiver and mount the vapour source in an offset position as shown in Fig. 1[2]. Sputtering electrodes can then be arranged with vapour sources for deposition of multi-layers. The vacuum pump used on this latter apparatus must be capable of obtaining low gas pressures for evaporation (0·1 micron mercury) and operate at high pressures (0·1 mm. mercury) with a controlled gas leak into the chamber during sputtering. Suitable pumps, commonly known as booster-diffusion pumps, are commercially available for this purpose.

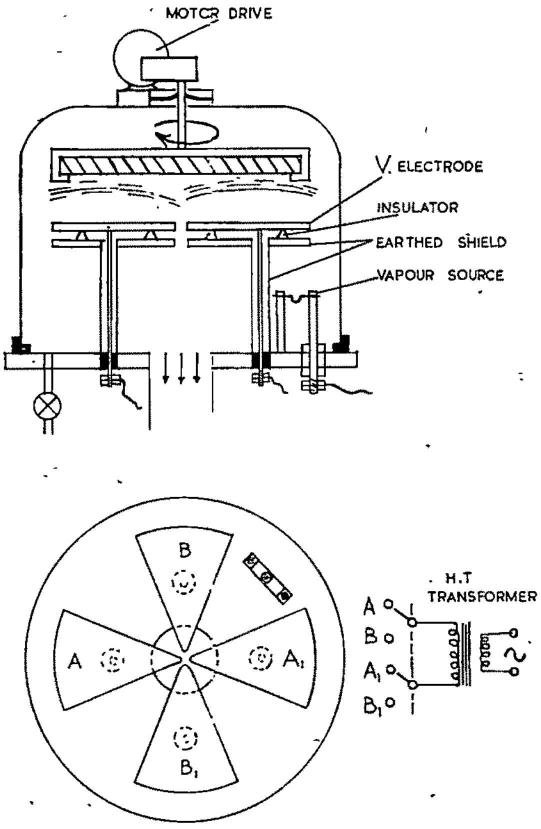

Fig. 1. Sputtering apparatus with V-electrodes

The new sputtering apparatus is being used in my laboratory for: (i) preparing durable multi-layer interference filters consisting of sputtered metal oxide films laminated with vacuum-evaporated magnesium fluoride films (titanium oxide films prepared in the laboratory by sputtering in pure oxygen have been found to have a refractive index of about 2·5 and are highly tenacious to glass); (ii) the sputtering of transparent conducting gold films on sputtered bismuth oxide base layers; the properties of this film combination have been described by Gillham and Preston[3] and others[4].

It should also be possible to prepare coatings of alloys and mixtures by sputtering from two V-electrodes of dissimilar metals operated from an a.c. supply.

A full account of the new sputtering technique and its uses will be published shortly. Acknowledgments are made to Mr. G. Siddall for his assistance in the construction of a prototype apparatus, and to Mr. A. S. D. Barrett, technical director, for permission to publish this communication.

Radioactivation Analysis of Phosphorus in Iodine

An important method in the preparation of pure silicon for semiconductor devices is the silicon iodide process[1]. In this method silicon tetraiodide is formed from the elements and purified by fractional distillation before being decomposed by passage over a heated tantalum filament. We have found by radioactivation analysis[2] that the predominating *N*-type impurity in silicon produced by this method in our laboratory is phosphorus, and that its concentration seems to be largely independent of the phosphorus content of the 'crude' silicon. This could be explained if there was an appreciable phosphorus-level in the iodine used, as the mass ratio of silicon to iodine in the above reaction is about one to twenty. Therefore we developed the following method for estimating the phosphorus content of iodine.

On irradiating iodine which contains phosphorus in a thermal neutron flux, the following nuclear reactions take place.

$$^{127}\mathrm{I}\,(n,\gamma)\,^{128}\mathrm{I} \xrightarrow{\beta'+\gamma} {}^{128}\mathrm{Xe}\ (t_{1/2} = 25\cdot0\ \mathrm{min.}) \qquad (1)$$

and

$$^{31}\mathrm{P}\,(n,\gamma)\,^{32}\mathrm{P} \xrightarrow{\beta'} {}^{32}\mathrm{S}\ (t_{1/2} = 14\cdot3\ \mathrm{days}) \qquad (2)$$

The half-life values show that if we allow sufficient time for the iodine activity to die away, the activity in the specimen will be entirely due to phosphorus and other long-lived impurities present. This is of considerable advantage in the handling of the activated samples, as no radiation shielding is required.

The reaction used for determining the phosphorus content is the following:

$$2\mathrm{P} + 5\mathrm{I}_2 + 8\mathrm{H}_2\mathrm{O} = 10\mathrm{HI} + 2\mathrm{H}_3\mathrm{PO}_4 \qquad (3)$$

It is of paramount importance that the carrier added to the irradiated sample be in the same chemical form as the active element which is to be determined. This is achieved in the above reaction, as the phosphorus, whether present originally as the element or the iodide, ends up as an orthophosphate ion. The method also has the rather novel feature that the inactive phosphorus takes part in the reaction and, after conversion to phosphate, also acts as a carrier.

The details of the method are as follows. About 0·5 gm. samples of iodine were sealed in silica ampoules and irradiated for a week in the pile at Harwell together with 30 mgm. of diammonium hydrogen phosphate to act as a standard. On return, the ampoules were allowed to stand for a day to let the activity due to the iodine decay and were then cracked open and crushed in a percussion mortar. The mixture was transferred with great care into about 20 ml. of distilled water containing a suspension of 55 mgm. of red phosphorus (a weight in excess of the amount required for the reaction). As the reaction proceeded, iodine was dissolved in the hydriodic acid solution, giving an intense colour. The solution was warmed on a water bath until the iodine coloration had completely disappeared. The residual red phosphorus was then dissolved by adding excess inactive iodine, and standing the solution on the water-bath overnight. The fragments of the silica ampoule were then removed by filtration and the filtrate treated with hydrogen peroxide. Iodine crystals slowly appeared as the iodide complex was broken down and the iodine solubility consequently decreased. These crystals were filtered off. Chloroform was then shaken with the filtrate in a separating funnel to remove final traces of iodine. The procedure was repeated until the final aqueous solution was colourless.

The phosphate was then determined as the magnesium pyrophosphate in the same manner as we have previously reported[2]. Three methods were used for establishing the identity of the activity thus isolated. Absorption and decay measurements were made showing it to be a pure β-radiation with a half-life of fourteen days, and in some cases the solution and precipitation stages were again repeated, the results showing no loss in activity per gram. These facts indicate that, using the above technique, the phosphate isolated is radiochemically pure. The overall efficiency of the method is 70–80 per cent.

If one assumes that the maximum efficiency of the counting system is 25 per cent and that its detection limit is 20 counts per min. above background, then it can be shown that, for irradiation for a week at a pile factor of 10, the limit of the method is about 0·003 part per million on a gram sample.

Phosphorus concentrations, which we have measured in iodine from various sources, have been found to vary between 10 and 0·1 parts per million. A sample of 'Analar' grade iodine was found to contain 0·18 p.p.m. of phosphorus.

We are indebted to colleagues in this laboratory for encouragement and assistance.

Crystal Structure of *p*-Chlorbenzene Iododichloride

The unexpected bond distances observed by Archer and van Schalkwyk[1] in benzene iododichloride have indicated a class of organic compounds about which few structural data are at present available. We have therefore sought to confirm their findings by the examination of a related compound, *p*-chlorbenzene iododichloride.

Light-yellow needles of this compound are obtained by passing dry chlorine into a dry chloroform solution of *p*-iodochlorbenzene. Like other iododichloride compounds with an electrophilic group in the *para* position, giving rise to a dipole moment directed away from the iodine atom, *p*-chlorbenzene iododichloride appears to be moderately stable and certainly more so than unsubstituted benzene iododichloride (Table 1). It seems possible that the tendency of electrons to drift away from the iodine atom partially increases the positive charge on the iodine and so makes possible a greater resonance stabilization of the molecule[4].

Single-crystal X-ray oscillation and Weissenberg photographs, taken with copper and molybdenum K_α radiations, indicate a triclinic unit cell: $a = 10\cdot1_0$; $b = 4\cdot13$; $c = 11\cdot0_3 \pm 0\cdot04$ A.; $\alpha = 96°\ 42'$; $\beta = 107°\ 27'$; $\gamma = 91°\ 12' \pm 36'$; where b is the needle axis. With the observed density, 2·31 gm./c.c., this corresponds to two molecules per unit cell. The centrosymmetric test[5] was used for deciding between the two alternative space groups. This shows clearly that the (*h0l*) projection must be centrosymmetric,

Table 1

[b] Calculated from values given in ref. 3.

and that therefore the space group must be $P\bar{1}$. The space group has agreed satisfactorily with more detailed considerations of the structure, which place the iodine atom at (0·040, 0·280, $\overline{0{\cdot}175}$).

The orientation of the molecules is such that there is very little atomic overlapping in the ($h0l$) projection. This projection is at present being refined to give accurate x and z co-ordinates for all the atoms. The y-co-ordinates are being determined from the ($hk0$) projection and from n-layer line data[6].

The main features of the present structure are in agreement with the reported dimensions and symmetrical linearity of the —ICl_2 group[1], with the third valency approximately at right-angles to it. Presumably dsp^3 or d^3sp bonds are formed, but not fully used. The plane of the —ICl_2 group appears to be more nearly that of the benzene ring than is the case in benzene iododichloride, where they are at right-angles. It is also clear that the main cohesive forces in the crystal are between the iododichloride groups.

Our results are the more interesting because a linear bond configuration around iodine is clearly not possible for the closely related cyclic compounds, such as that formed from o-iododichlor-benzoic acid by the elimination of hydrogen chloride[7].

Ultrasonic Relaxation in Unsaturated Aldehydes

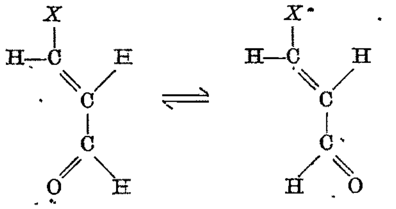
Recent measurements[1] of the absorption of ultrasonic waves in some unsaturated aldehydes over the frequency-range 100 kc./s. to 1 Mc./s. have shown that relaxation occurs in crotonaldehyde and cinnamaldehyde. If α is the absorption coefficient relating to the excess pressure of the sound wave, then in the absence of relaxation the quantity (α/f^2) remains constant with frequency, f. In the region of a single relaxation having a relaxation time, τ, we have[2]:

$$\frac{\alpha}{f^2} = \frac{A}{1 + (f/f_c)^2} + B \tag{1}$$

provided that the velocity dispersion is negligible. Here $f_c = 1/2\pi\tau$, and the parameters A and B depend upon temperature.

A decrease in the quantity (α/f^2) from its low-frequency value was found for crotonaldehyde and for cinnamaldehyde towards the upper end of the above frequency-range. No such change was found for acrolein.

We attributed the relaxation in crotonaldehyde ($X = CH_3$) and cinnamaldehyde ($X = C_6H_5$)[1] to perturbation by the sound wave of the equilibrium



(2)

These planar configurations are stabilized by resonance, and we suggested that the relaxation in acrolein occurs at frequencies greater than 1 Mc./s.

We have now extended this work by measuring the absorption of sound waves in these liquids at frequencies up to 100 Mc./s. The results confirm the previous explanation and are shown in Fig. 1. The parameters of the relaxations evaluated from the ultrasonic data are given in Table 1, which includes the velocity of sound, c, and the maximum absorption per wave-length due to the relaxation, $\mu_m = \frac{1}{2} Acf_c$.

In order to derive the parameters for acrolein, measurements are required at frequencies greater than 100 Mc./s., and we are in progress of obtaining these with our present apparatus. We are also studying the behaviour in these and related liquids over an extended temperature-range.

It is of interest to note that construction of the scaled molecular model for the ketone, mesityl oxide

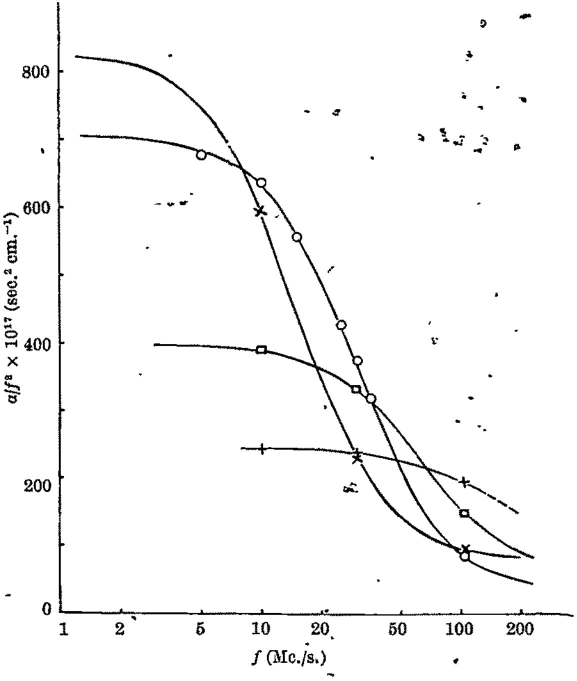


Fig. 1. Sound absorption in acrolein (+ — + —), crotonaldehyde (○—○—) and cinnamaldehyde (×—×—) at 25° C., and in crotonaldehyde (□—□—) at 50° C. The points are experimental, and the curves are calculated from equation (1) using the values of the parameters given in Table 1

Table 1

Liquid	T ° C.	$A \times 10^{17}$ sec.^{2} cm^{-1}	$B \times 10^{17}$ sec.^{2} cm.$^{-1}$	f_c (Mc./s.)	$c \times 10^{-5}$ cm. sec^{-1}	$\mu_m \times 10^2$
Crotonaldehyde	25 50	674 338	32 60	30 0 61 4	1 268 1 165	1·28 1 21
Cinnamaldehyde	25	746	80	15·1	1 561	0 88

[$(CH_3)_2C : CH\,CO\,CH_3$], shows that the higher-energy state to the right of the corresponding equilibrium (2) is untenable owing to the size of the interacting CH_3 groups. In accordance with this, we have not observed a relaxation in this liquid. Over the frequency-range 100 kc./s. to 1 Mc./s. we found previously that $(\alpha/f^2) = 35 \times 10^{-17}$ sec.^{2} cm.$^{-1}$ at 25° C. The value $(\alpha/f^2) = 36 \times 10^{-17}$ sec.^{2} cm.$^{-1}$ at 100 Mc./s. has been obtained in this laboratory by Mr. E. H. Heasell, to whom our thanks are due.

We acknowledge financial assistance from the Department of Scientific and Industrial Research in support of this research programme. We also appreciate the interest shown in this work by the Koninklijke/Shell-Laboratorium, Amsterdam, by which one of us (M. S. G.) is employed.

Coupled Oxidation of Keto-Acids with Glutathione

When glutathione is oxidized by copper ions or the cytochrome c – cytochrome-oxidase system in the presence of pyruvate, the added pyruvate is partially oxidized to acetic acid and carbon dioxide[1]. It was suggested that this reaction occurred by the production of a hemimercaptol compound between pyruvate and glutathione which is oxidized instead of free glutathione. Slater[2], disproving the hemimercaptol hypothesis, emphasized a model similar to that found by one of us[3] for the coupled oxidation of pyruvate by ascorbic acid, which involves the intermediate production of hydrogen peroxide. But the two points made by Slater in support of his postulate have been found to be inconsistent: (1) the chromatic effect of the methylglyoxal – glutathione complex in the ultra-violet, not shown by the pyruvate – glutathione complex, is mainly due to the enediol compound in equilibrium with the thioester resulting from the interaction[4]; enediols and thioesters are not likely to be produced by the interaction of glutathione with pyruvate, which forms only mercaptols; (2) the effect of catalase has been thoroughly investigated and we have been unable to reproduce the inhibitory effect reported by Slater. Moreover, (3) we now present evidence that in our experimental conditions a complex between glutathione and pyruvate is actually formed.

As Fig. 1 shows, the presence of 0·2 mgm. catalase does not appreciably affect the coupled oxidation of pyruvate. Similar results are obtainable by changing the concentration of the reactants or increasing the amount of catalase up to 0·5 and 1 mgm.

In order to test whether, in our conditions of dilution and pH, pyruvic acid is really bound to glutathione, we have taken advantage of Schubert's finding that in slightly alkaline solution the nitroprusside reaction of an R—SH complex with carbonyls is depressed[5]. Fig. 2 shows that this is the case also with glutathione and pyruvate, and curve 3 represents the curve obtained with the amounts of reactants used in the present experiments. Nitroprusside was added 10 min. after mixing the glutathione solution with the other reactants. The photometric readings were taken in a Coleman spectrophotometer using square cuvettes with prisms leaving a layer of 0·1 cm. cell-length. The unstable coloured reaction was followed under controlled conditions of time.

The coupled oxidation of pyruvate with glutathione occurs also with other keto-acids, though there are some peculiar differences (Table 1). In any event, when the coupled oxidation occurs, it is not appreciably modified by the presence of catalase.

Though the inactivity of catalase seems unquestionable, nevertheless this finding should not be taken as a conclusive indication that the coupled oxidation goes through the hemimercaptol complex; indeed, the peroxidative activity of catalase is well known[6]. The hemimercaptol hypothesis may still hold as a tentative explanation, being supported by the following considerations: (1) the activity of the cytochrome c – cytochrome-oxidase catalytic system, which does not produce peroxide; (2) the peculiar

behaviour of cysteine, which, forming a thiazolidine ring with pyruvate, is effective only in part, presumably in the form of an addition product; (3) the known ability of mercaptans to give hemimercaptols with carbonyl functions; (4) the actual production of a complex between glutathione and pyruvate in our conditions.

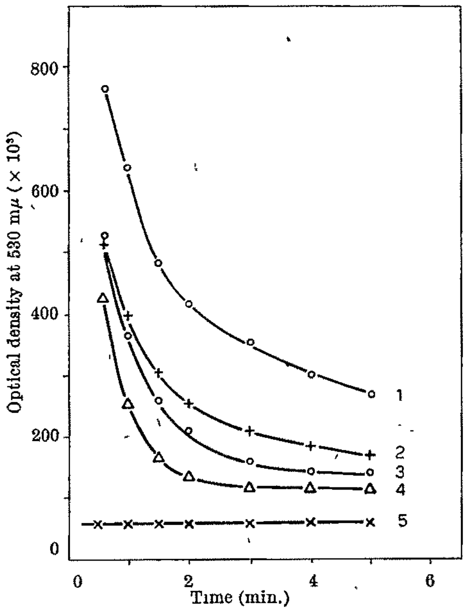

Fig. 2. Nitroprusside reaction of glutathione in the presence of different amounts of pyruvate. Conditions as in Fig. 1, with cupric chloride omitted. (1) Glutathione alone; (5) nitroprusside alone; (2), (3), (4), as (1) with 0·02, 0·04, 0·1 m.mol respectively of added pyruvate. At zero time, 0·2 ml. of 25 per cent nitroprusside was added to the test solution

At present, since the discovery of coenzyme A and lipoic acid, and of all the reactions leading to the oxidative decarboxylation of pyruvate, the resemblance between the coupled oxidation of glutathione with keto-acids and their biological oxidation by thiamine derivatives is, of course, out of date. Nevertheless, some biological oxidations seem to follow this path[7].

Anticoagulant Specificity and Physiologically Inactive Beta-Prothromboplastin

A SMALL number of hæmophilic patients at first benefit by blood or plasma transfusions but later develop in their blood an anticoagulant which renders further transfusions temporarily ineffective. It is believed that the anticoagulant is an antibody due to the transfused antigen[1], but positive precipitin tests have been obtained infrequently.

A seven-year old boy, *MJ*-1, whose plasma was completely deficient in β-prothromboplastin (*P.T.C.*[2] or Christmas-factor[3]) had received nine blood transfusions. When examined by us for the first time nine months after the last transfusion, his plasma contained a potent anticoagulant which inhibited the formation of blood thromboplastin. It was thought that the anticoagulant was active against β-prothromboplastin, but serological tests were negative and the following procedure was developed: β-prothromboplastin from plasma or serum was adsorbed on barium sulphate suspension. The adsorbate was washed with 0·15 *M* sodium chloride until free of protein and drained. To the deposit 1 ml. of the isolated anticoagulant from plasma of *MJ*-1 was added and stirred frequently for 1 hr. at room temperature. The supernatant was tested for anticoagulant activity with a thromboplastin generation test[4] or by thrombin formation[5]. The results obtained are given in Table 1.

Table 1. MODE OF ACTION AND SPECIES SPECIFICITY OF AN ANTICOAGULANT AGAINST BETA-PROTHROMBOPLASTIN

Anticoagulant treated with barium sulphate adsorbate prepared from:	Remaining activity as percentage of original anticoagulant
(*A*) Untreated barium sulphate suspension	100
(*B*) Normal human oxalated plasma	44, 39, 23, 32, 34, 28
(*C*) Normal human oxalated plasma free of β-prothromboplastin	100
(*D*) Normal human serum	32
(*E*) Normal rabbit plasma	76
(*F*) Congenital β-prothromboplastin deficiency (*MB*-1)	100
(*G*) Congenital β-prothromboplastin deficiency (*MA*-2) 51 and 69 days after plasma transfusion	49, 50
(*H*) Congenital β-prothromboplastin deficiency (*MD*-1) 36 months after blood transfusion	92

From these results, it is seen that the anticoagulant reacts specifically with β-prothromboplastin of human origin (*B* and *D*), but shows little activity with that of rabbit's plasma (*E*). The anticoagulant is not removed by barium sulphate adsorbate prepared from human plasma which has been freed artificially of β-prothromboplastin (*C*).

Barium sulphate adsorbates were prepared from plasma of several patients (*F*, *G*, *H*). *MJ*-1 and *MA*-2 do not suffer from different deficiencies because admixture of their plasma freed of inhibitor did not result in any correction of the clotting deficiency. *MB*-1 has never had a blood transfusion; *MA*-2 and *MD*-1 had received a number of blood plasma and serum transfusions which were always beneficial to them clinically, and laboratory tests showed no evidence of an inhibitor in their blood. Whereas barium sulphate adsorbates prepared from plasma of patients *MB*-1 and *MD*-1 removed little or no anticoagulant activity (*F* and *H*)—as expected—the barium sulphate adsorbates prepared from plasma of *MA*-2 removed 50 per cent of anticoagulant activity; which is only a little less than that removed by normal plasma adsorbates. This puzzling finding cannot be due to transfused β-prothromboplastin, because it was not detectable by coagulation studies.

Patients who have prothromboplastin deficiencies present instances of genetically determined abnormalities of protein synthesis. Our observations suggest the following conclusions. It seems that a proportion of such patients can produce substances closely related to the prothromboplastins in their antigenic properties but which are inactive in the formation of blood thromboplastin. Other patients are unable even to produce a prothromboplastin with antigenic properties or physiological activity. Because of this they are the most likely ones to develop antibodies following the transfusion of the particular prothromboplastin they lack. The adsorbate technique shows to which of these two groups a patient belongs. These ideas are in agreement with the observation that only a fraction of hæmophilics develop anticoagulants and that these suffer severe clinical disease, thus implying that they have a complete prothromboplastin deficiency[6].

Complete clinical and laboratory studies will be reported elsewhere. This investigation was carried out with the financial support of the National Health and Medical Research Council of Australia.

Action of Chlorpromazine on Oxidative Phosphorylation of Liver and Brain Mitochondria

Investigations of recent years have shown that mitochondria, irrespective of their source, are the site of oxidative phosphorylation; but it is not known to what extent the metabolism of these structural units is specific for a particular organ.

We wish to report on the difference in action of chlorpromazine (10-(3-dimethylaminopropyl)-2-chlorphenothiazine) on oxidative phosphorylation in mitochondria from liver and brain, and on some properties of these particles from the two organs observed in the course of this work (cf. ref. 1). The mitochondria from liver were prepared according to, and from brain by a modification of, the method of Schneider[2]. Chlorpromazine inhibited the phosphorylation accompanying the oxidation of rat liver mitochondria with α-ketoglutarate, succinate, glutamate and pyruvate + malate as substrates, whereas it did not do so with mitochondria from rat brain cortex (Table 1). Essentially the same results were obtained with particles from guinea pig and monkey brain cortex. 2,4-Dinitrophenol was effective in suppressing phosphorylation with mitochondria from both organs.

In order to investigate the site of uncoupling by chlorpromazine, phosphorylation resulting from the oxidation of cytochrome *c* was studied with ascorbic acid or adrenaline as substrates according to the procedure of Maley and Lardy[3]. Table 2 shows that the presence of 2×10^{-4} *M* chlorpromazine uncoupled oxidative phosphorylation with liver mitochondria. In some cases phosphorylation was completely inhibited by the drug, whereas the oxidation was either the same or greater than that of the controls. When the experiment was repeated with mitochondria from rat brain cortex in the absence of chlorpromazine, little, if any, phosphorylation was obtained with cytochrome *c* and either ascorbate or adrenaline, but oxidation was unimpaired.

Table 1. Effect of Chlorpromazine on Oxidative Phosphorylation of Mitochondria from Liver and Brain Cortex (Rat)

	Liver			Brain		
	ΔP (μmoles)	O (μatoms)	P : O	ΔP (μmoles)	O (μatoms)	P : O
α-Ketoglutarate	29·3	10·4	2·8	7·9	2·6	3·0
+ chlorpromazine	21·9	11·6	1·9	6·6	2·2	3·0
Succinate	24·9	11·3	2·2	8·2	5·0	1·6
+ chlorpromazine	12·1	10·5	1·1	7·1	4·6	1·5
Pyruvate + malate	20·7	8·2	2·5	14·7	5·5	2·7
+ chlorpromazine	13·2	7·5	1·7	15·1	5·5	2·8
Glutamate	31·3	13·4	2·3			
+ chlorpromazine	19·8	11·6	1·7			

The reaction vessels contained (in μmoles): phosphate buffer, *p*H 7·4, 60; magnesium sulphate, 20; adenosine triphosphate, 6·5; cytochrome *c*, 0·02; sodium fluoride, 10–15; substrate; mitochondrial suspension, 0·5 ml. (average nitrogen, 1·3 mgm.); glucose, 50; hexokinase (Pabst), 0·4 mgm; and potassium chloride solution (0·15 *M*) to a final volume of 3 ml. (when brain mitochondria were used, diphosphopyridine nucleotide at 0·2 mgm. per flask was added). Levels of substrates: α-ketoglutarate, 30; succinate, 30; glutamate, 60; pyruvate, 60 + malate, 3. Chlorpromazine = 2×10^{-4} *M*. Temperature 37° for liver, 30° for brain, incubation, 20–30 min. in air.

Exposing liver mitochondria to hypotonic sucrose with low levels of cytochrome *c*[4] resulted in phosphorus/oxygen ratios of 0·5–0·8 for the one-step oxidative phosphorylation. Practically no phosphorylation was obtained with brain mitochondria under the same experimental conditions. (Phosphorus/oxygen ratios averaging 0·1 (50 min. incubation) were obtained in experiments with commercial horse heart cytochrome *c* (Sigma). Upon column purification[5], this cytochrome *c* or cytochrome *c* prepared from beef brain gave higher phosphorylation values (phosphorus/oxygen ratios averaging 0·25), which were still far below those obtained with liver mitochondria.)

The observation that chlorpromazine appeared to uncouple oxidative phosphorylation in liver at the cytochrome *c* step was further supported by preliminary findings that the drug had no effect on phosphorus/oxygen ratios when ferricyanide was used as the electron acceptor. The failure of chlorpromazine to affect brain cortex mitochondria may be connected with their poor utilization of external

Table 2. Phosphorylation coupled to the Oxidation of Cytochrome *c*

			2×10^{-4} *M* chlorpromazine		
ΔP (μmoles)	O (μatoms)	P : O	ΔP (μmoles)	O (μatoms)	P : O
Ascorbic acid (30 μmoles)					
5·3	6·5	0·81	3·1	6·9	0·45
3·4	6·8	0·50	0	7·6	0
4·9	4·9	1·0	1·1	5·1	0·22
Adrenaline (10 μmoles)					
5·8	5·8	1·16	0	4·9	0
4·6	5·6	0·82	0	7·4	0

The reaction vessels contained in addition (in μmoles): adenosine triphosphate, 6; phosphate buffer, *p*H 7·4, 30, magnesium sulphate, 30; sodium fluoride, 40; cytochrome *c* (Sigma), 0·3; glucose, 40, hexokinase, 0·4 mgm.; liver mitochondrial suspension, 0·5 ml. (average nitrogen, 1·7 mgm.); and sucrose solution (0·25 *M*) to a final volume of 3·0 ml. Gas phase, air; incubation at 30° with adrenaline for 10 min., with ascorbic acid 20 min.

cytochrome *c* for oxidative phosphorylation. This may point to a basic difference in the surface configuration of these structural elements of liver and brain cells. It may also be argued that the observed uncoupling of oxidative phosphorylation in liver mitochondria by chlorpromazine is secondary to the effect of the drug on mitochondrial structure.

Effects of Pituitary Growth Hormone on the Insulin and Hyperglycæmic-glycogenolytic Factor extractable from the Pancreas of Obese-Hyperglycæmic Mice

IN two separate experiments it has been found that, 24 hr. after the administration of bovine pituitary growth hormone to mice with the hereditary syndrome of obesity and hyperglycæmia (1 mgm. of growth hormone per mouse), changes had occurred in the amounts of insulin and hyperglycæmic-glycogenolytic factor extractable from the pancreas using a standardized acid alcohol technique[1]. In each experiment values for insulin and hyperglycæmic-glycogenolytic factor values were compared in the following four groups of animals (ten or twelve animals per group): obese-hyperglycæmic mice and their non-obese sibs treated with growth hormone, and two groups of the same description but not treated with growth hormone.

The growth hormone treatment resulted in significant rises of 37 and 169 per cent in the average (non-fasting) blood-sugar level in the groups of obese-hyperglycæmic mice above pre-injection non-fasting levels. For the hyperglycæmic-glycogenolytic factor assays, concentrations of test materials were measured on a logarithmic scale, and the above rises were associated with logarithmic increases in the factor of 1·52 and 2·42 respectively, relative to untreated obese controls. The insulin extractable from the pancreas decreased by 48 and 86 per cent in the two experiments. No consistent changes were observed in the hyperglycæmic-glycogenolytic factor or insulin extractable from the pancreas of the non-obese mouse following injection of growth hormone.

Rise of the concentration of glucose in pancreatic blood plasma results in increased release of insulin by the pancreas in the rat[2] and in the dog[3,4]. The fall in the extractable insulin of the pancreas which followed the rise in blood-sugar level in the obese-hyperglycæmic mouse, treated with growth hormone in our experiments, may signify that the pancreas of these animals is not able, following a sudden increase in demand, further to increase insulin production[5] to compensate for the increased rate of release. The alternative explanation for the fall in the extractable insulin, namely, that it resulted principally from decreased insulin production without increased insulin secretion, is not, in our opinion, so well supported.

Mice with the obese-hyperglycæmic syndrome have a turn-over of liver glycogen several times faster than their non-obese sibs[6] and have six times as much liver phosphorylase activity as their non-obese litter-mates (Shull, K. H., and Mayer, J., unpublished work). In view of Sutherland's findings concerning the action of hyperglycæmic-glycogenolytic factor on liver phosphorylase[7], these observations are consistent with the previously postulated hypothesis[8] of a hypersecretion of the factor in these animals. These obese mice are unusually sensitive to the hyperglycæmic action of growth hormone[9], which has been observed to cause the release of a hyperglycæmic factor by the pancreas in rats and cats[10] and in dogs[3]. In spite of apparent differences between the conditions of action of this agent and the extracted hyperglycæmic factor of pancreas[11], the hypothesis that growth hormone in the obese hyperglycæmic mouse leads to a rise in blood-sugar level due to a hyperglycæmic factor originating in the pancreas is still supported. The observed co-existent increase in the hyperglycæmic-glycogenolytic factor extractable from the pancreas apparently indicates that growth hormone administered to the obese hyperglycæmic mouse caused the rate of production of extractable hyperglycæmic-glycogenolytic factor to exceed its rate of disappearance from the pancreas. Experiments which are in progress will, perhaps, provide more information than is available at present on these processes.

Mechanism of Anorexia in Vitamin-deficient Hyperphagic Animals

RECENT findings[1] have demonstrated that the ventromedial hypothalamic nuclei act as 'satiety' brakes which, in response to certain stimuli (particularly metabolic), inhibit a constantly activated 'feeding' mechanism. This mechanism, in turn, appears to be initiated at the level of the anterolateral nuclei[2]. Destruction of the ventromedial nuclei does not increase hunger (as measured by rate of ingestion); it shortens the pauses between 'meals' which, in normal animals, steadily increase during the day so as to constitute a 24-hr. feeding cycle marked with a definite 'satiety' pattern[1]. A method for the destruction of these centres in the rat[3], the mouse[4] and other species is through the use of stereotaxic instruments. In the mouse, it has also been shown recently[5] that administration of gold thioglucose leads to obesity through injury to the ventromedial nuclei. Such mice and 'hypothalamic' rats and mice can thus be used for elucidating whether vitamin deficiencies act by permanently activating the 'satiety' mechanism or by inactivating the 'feeding' mechanism. For example, one could visualize that thiamine deficiency, the anorexic effect of which is classic, permanently activates the ventromedial nuclei because of the constant elevation of blood concentration of intermediaries of carbohydrate metabolism, or inactivates the feeding mechanism through the action of toxic accumulation of noxious products or because of the lack of carboxylase *per se*.

The following experiment was carried out. Twenty-one adult female mice were studied; eleven of these were obese, having been made hyperphagic by a single intraperitoneal injection (1 mgm./gm.) of gold thioglucose 147 days previously. The mean weight of these eleven hyperphagic mice was 50 gm. (range 40–63 gm.), and that of the ten controls was 32 gm. (range 29–36 gm.). All the mice were fed a synthetic diet[6] plus essential vitamins for a conditioning period of twelve days; then the eleven hyperphagic mice were fed restricted amounts of this diet so that after a restriction period of fourteen days their weights (mean 33 gm., range 31–34 gm.) approximated to those of the non-hyperphagic controls. At this point, half the control mice and six of the eleven hyperphagic mice were fed a thiamine-deficient diet until there were no survivors; the other controls and the other five hyperphagic mice being fed the diet plus thiamine for the same period.

The hyperphagic thiamine-deficient mice died earlier (20·5 ± 4·4 days) than the non-hyperphagic thiamine-deficient controls (24·2 ± 2·6 days); this difference was statistically significant ($p < 0{\cdot}05$ but $> 0{\cdot}02$). By the time the last of the mice receiving the thiamine-deficient diet had died, the hyperphagic mice that had been fed the diet plus thiamine had returned to approximately the same weights as previously, their mean weight at the end of the experiment being 52·4 gm. (range 40–61 gm.).

It is clear from the results that, in this case, the hyperphagic tendency of the gold thioglucose animals was instantly eliminated by the deficiency. Indeed, the deficiency—and the anorexia—were in effect earlier in these animals than in their controls, doubtless because for a few days the caloric intake of the hyperphagic animals was greater, thus increasing the requirement[7]. In view of the absence of functional 'satiety' tissue[5], the deficiency must have caused anorexia through direct inactivation of the 'feeding' mechanism.

The specificity of this effect of thiamine deficiency is further demonstrated by the following experiment involving a chronic deficiency of vitamin A. Requirement for this vitamin is not related to caloric intake[8], nor is decrease in food intake the earliest observable effect of the deficiency[9]. Sixteen 21-day old female rats were placed at weaning on a vitamin A-deficient semi-synthetic diet[10] on which their mothers had been maintained during lactation. Eight controls received 1,200 I.U. of vitamin A per week whereas the experimental group received only one dose of 100 I.U. at weaning. Three and a half months later, this group exhibited a permanently keratinized vagina, eyelids partly denuded and red, and a body-weight steady at 50 gm. below the control-level. Both groups were subjected to hypothalamic lesions. In each group, five animals became markedly hyperphagic. In particular, in the deficient group, the five successfully operated animals increased their weights within the next two months by 70–200 gm. (maximum weight recorded 545 gm.). Having reached the maximum weight, the animals then lost weight and survived 1–2·5 months, a total survival no less and probably greater than that of unoperated deficient animals maintained in comparable conditions. Thus, in this type of deficiency, with presumably no direct effect on the feeding mechanism, removal of the satiety centres leads to marked and lasting hyperphagia. This observation would also suggest that considerable fat deposition can be accomplished in the face of advanced depletion of vitamin A, which would tend to preclude an active role for vitamin A in fatty acid synthesis.

The experiments reported above indicate that the use of hyperphagic animals in nutritional deficiency studies can permit the beginning of an analysis of the mechanism of the anorexia associated in various degrees with many of them.

Lactose as a Lipotropic Agent

INCORPORATION of a small amount of lactose in the diet of young albino rats increases their food intake and they grow better than the control rats fed on sucrose. This increased food intake leads to greater weight and increased fat content of their liver and kidney[1]. If the food intake of lactose-fed rats is equalized to that of the sucrose-fed rats by the paired-feeding technique, the liver and kidney fat content decreases in the lactose-fed rats.

A batch of forty-eight young albino rats weighing 30–35 gm. was divided into four groups, one group receiving a lactose-free complete diet with added cystine (casein 15, sucrose 58, coconut oil 15, salt mixture 4, cod-liver oil 5, cystine 0·4 and vitamin mixture except choline), and the other three groups receiving the same diet except for the partial replacement of sucrose by 10, 20 and 30 per cent lactose.

Table 1. Distribution of choline, sphingomyelin, lecithin, cephalin and phospholipid (in mgm./gm.) of wet weight of tissue and fat per cent in rats fed different amount of lactose (C_1, C_2, C_3 groups receiving 10, 20, 30 per cent lactose) as compared with that of sucrose-fed rats (C_0 group)

Analysis	Liver C_0	Liver C_1	Liver C_2	Liver C_3	Kidney C_0	Kidney C_1	Kidney C_2	Kidney C_3
Choline	1·32	2·02	2·31	2·51	1·57	2·04	2·57	2·75
Sphingomyelin	0·75	0·69	0·50	0·41	0·91	0·75	0·58	0·44
Lecithin	8·0	12·7	14·9	16·3	9·5	12·8	16·5	17·9
Cephalin	8·9	8·3	12·8	10·3	11·9	13·7	14·9	12·2
Phospholipid	16·9	21·0	25·6	26·6	21·4	26·5	29·8	30·1
Fat (per cent)	11·3	10·1	10·4	9·7	12·4	10·4	10·4	9·8

All the lactose-fed rats were pair-fed with the C_0 group eating the sucrose diet. After four weeks of experimental feeding they were killed and livers and kidneys analysed for fat, choline, phospholipid and sphingomyelin[2] (see Table 1).

The lactose-fed rats had greater choline and phospholipid and less fat and sphingomyelin content n liver and kidney. This experiment shows that actose not only acts as a sparer of choline, but also as a lipotropic agent by virtue of this effect, provided the food intake is controlled to the same level. This has an important bearing on the kwashiorkor syndrome, where lack of milk and absence of lactose n the diet of the young after early weaning may be esponsible for the fatty liver, which is caused as a esult of the lack of choline-sparing and lipotropic effects of lactose. The mechanism of increased food ntake in lactose diet is being investigated.

I am indebted to Dr. S. Datta, director of veterinary ervices and animal husbandry, West Bengal, for his nterest and valuable suggestions.

Utilization of the Carboxyl Carbon of L-Phenylalanine for the Synthesis of the Amino-acids of Silk by *Bombyx mori*

PREVIOUS observations in this laboratory conerning the content of free amino-acids in the silk land of *Bombyx mori* seemed to indicate that silk lanine might be derived from phenylalanine. In rder to check this possibility, it was decided to nject silkworms with L-phenylalanine labelled with arbon-14 in the carboxyl group, before they spin heir cocoons.

The L-phenylalanine was prepared from glycine abelled with carbon-14 in the carboxyl group, following the method of Bergmann *et al.*[1]. Acetylglycine was allowed to react with benzaldehyde and the zlactone obtained was coupled with L-glutamic acid ; he product of the reaction was hydrogenated and he acetyl-L-phenylalanyl-L-glutamic acid was separated by crystallization from the acetyl-D-phenyllanyl-L-glutamic acid. After hydrolysis of the cetyl-L-phenylalanyl-L-glutamic acid, the two aminocids were separated on a starch column following tein and Moore's procedure[2]. The radioactive -phenylalanine was crystallized in water/ethanol and he purity checked by paper chromatography phenol/water ; butanol/N hydrochloric acid) ; Kjeldahl nitrogen analyses (8·61 per cent; theor., 8·48 per cent), and optical activity determination ($[\alpha]_D^{20} = -34\cdot5°$, litt. $-35\cdot1°$). The scanning of the paper chromatograms showed that the radioactivity was exclusively localized at the phenylalanine spots. That the radioactivity was indeed in the carboxyl group of the radioactive phenylalanine was shown by ninhydrin decarboxylation following the method of van Slyke *et al.*[3] (see Table 1).

0·2 mgm. of this carboxyl-labelled L-phenylalanine was injected into each of ten silkworms after they had stopped eating and were ready to spin their cocoons. It must be emphasized that, at this time, the silk glands are already swollen with secretion.

Fibroin was isolated from the ten cocoons, following the procedure described by Dunn *et al.*[4]. The fibroin was then hydrolysed by refluxing in 32 per cent hydrochloric acid for eight hours. The tyrosine, glycine and alanine were isolated following Stein and Moore's method[5].

The glycine was isolated as the *p*-azobenzene sulphonate and the alanine as the nitronaphthalene sulphonate ; these sulphonates were recrystallized in water. The amino-acids were obtained by passing the sulphonates on an 'Amberlite' *IR*-120(H) resin and then eluting with 3 N ammonia ; the amino-acids were crystallized in water/ethanol/ethyl ether and found to be chemically pure by paper chromatography (phenol/water ; butanol/N hydrochloric acid) and Kjeldahl nitrogen analyses (18·75 per cent for the glycine and 15·75 per cent for the alanine ; theor. 18·66 and 15·72 per cent respectively). Both glycine and alanine were radioactively inactive (Table 1).

The tyrosine was purified by starch chromatography following Stein and Moore's procedure[2]. The radioactivity of this purified tyrosine was determined, and the compound was found to be active. It was felt that it could not be precluded that the radioactivity of the tyrosine might be due to traces of the very radioactive phenylalanine that had been injected. To examine this possibility, ordinary phenylalanine was added to the purified tyrosine and the mixture separated by chromatography on a starch column. The eluted tyrosine was dissolved in sodium hydroxide solution and crystallized by addition of acetic acid to pH 5 and ethanol ; the radioactivity was again measured and found to be slightly higher than previously ; there was, moreover, no detectable radioactivity in the eluted phenylalanine. Both results show that the radioactivity of the tyrosine sample was not due to the contamination by carbon-14-phenylalanine and was most probably within tyrosine molecules. The chemical purity of the purified tyrosine was proved by paper chromatography

Table 1

	Specific activities*	
	Amino-acid (c./min./m.mole)	Carboxyl group of amino-acid (c./min./m.equiv.)
Injected L-phenylalanine	$13\cdot$[illegible]$ \times 10^6$ $\sigma = 1$ per cent	$13\cdot5 \times 10^6$ $\sigma = 1$ per cent
Silk glycine	0	
Silk alanine	0	
Silk tyrosine	$23\cdot$[illegible]$ \times 10^3$ $\sigma = 1$ per cent	$23\cdot8 \times 10^3$ $\sigma = 1$ per cent

* All determinations were performed on barium carbonate deposits.

(phenol / water; butanol / *N* hydrochloric acid) and Kjeldahl nitrogen analyses (7·75 per cent; theor. 7·73 per cent). The radioactivity of the isolated tyrosine was localized exclusively in the carboxyl group as it was entirely in the carbon dioxide evolved by ninhydrin decarboxylation (Table 1).

From these results, it is concluded that phenylalanine is converted to tyrosine by the silkworm and that the conversion is a fairly direct one, since the radioactivity was exclusively localized in the carboxyl group of the injected phenylalanine and the isolated tyrosine. About 15 per cent of the injected phenylalanine radioactivity was found in the tyrosine of the silk fibroin.

On the other hand, the carboxyl carbon of phenylalanine is not utilized for the synthesis of alanine or glycine of the silk by *Bombyx mori*; the tyrosine results make it very unlikely that the phenylalanine could not reach the site where such transformation occurs.

This work was nearly completed when Fukuda published results[6] showing that he had isolated radioactive tyrosine from silk after injection of 2-^{14}C-phenylalanine into silkworms; he found only a very small activity in glycine and alanine.

We wish to thank Ch. Jeuniaux for his help in looking after the silkworms and injecting them with the radioactive compound.

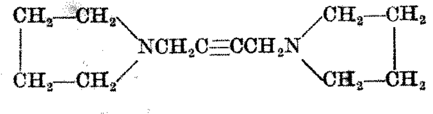
Tremor produced by Drugs

IN the routine screening of drugs in mice, we have found only ten out of ten thousand compounds which produce sustained tremor. One of these, 1-4 dipyrrolidino-2-butyne, 'Tremorine',



in doses of 5–20 mgm./kgm. produces tremor, salivation, meiosis, slight muscular weakness and rigidity lasting several hours. The effects are similar in mice, rats, guinea pigs, cats, dogs and monkeys. In the last-named species the picture is strikingly similar to human Parkinsonism. The antagonism of these effects is complete with various drugs used for treating Parkinsonism. Atropine, scopolamine and others are highly effective in small doses of 1–2 mgm./kgm. In contrast, hypnotics, anticonvulsants and ganglionic blocking agents were without effect on tremor in doses below those causing marked depression. It thus offers a specific method for the testing of possible anti-Parkinson agents.

Methantheline ('Banthine') controlled the parasympathetic signs of salivation and diarrhœa but had no effect on the tremor, demonstrating the distinct peripheral and central actions. The tremor appears to be primarily of subcortical origin. Decerebrate animals develop tremor after 'Tremorine'. The drug also causes a profound fall in body temperature. The chemical structure producing tremor is highly specific within this chemical type. Twenty analogues showed no such action. Other tremor-producing drugs are of widely diverse chemical structures. Nicotine tremor has been studied by Bovet *et al.*[1] and suggested as a test method for anti-Parkinson drugs. While this method is useful, the nicotine tremor is fleeting, has both central and peripheral components and is blocked by a number of drugs not effective in Parkinsonism[2]. Another drug, 'Harmaline', produces sustained tremors but no signs of parasympathetic involvement, and is not antagonized by a variety of anti-Parkinson drugs, blocking agents or sedatives.

It is hoped that the discovery of 'Tremorine' and its further study will reveal it to be a useful tool in the investigation of tremor and the search for more effective agents against Parkinsonism.

Auto-oscillations in Extracted Muscle Fibre Systems

IN the course of work on relaxing factors[1], Goodal and A. G. Szent-Györgyi[1] observed that with fibre showing less than maximal activity for the creatine phosphate – adenosine triphosphate relaxing system an auto-oscillation of tension developed if the creatine phosphate was increased to 30–100 m*M*. These oscillations (Fig. 1) were observed on several occasions under the above conditions. They are independent of a *p*H change from 6·8 to 5·9 which produces a 50 per cent fall of tension, as compared to 90 per cent for 'active fibres. However, it is not certain that this 'deactivation' is an essential part of the extraction procedure

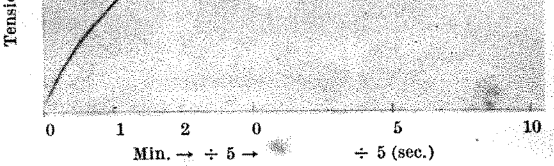

Fig. 1. Rabbit psoas muscle fibre extracted with 40 per cent ethylene glycol – water for seven days, developing oscillations in 4 m*M* adenosine triphosphate, 100 m*M* sodium creatine phosphate, 4 m*M* magnesium chloride, at *p*H 7·0. Drum-speed increased five times at each break in record

afterwards I found that 40 per cent ethylene glycol – water extraction at −5° C. produced oscillating fibres in a matter of a few days. The significant fact about such fibres appears to be their high elastic modulus.

The frequency, 2·8 sec.$^{-1}$, was 1·75 times the free oscillation of the recording lever alone, while with fibre coupled in the absence of substrate, it was about twice. Since, however, the elastic modulus falls by a factor of more than three times in the presence of adenosine triphosphate alone, it seems that the tension generator is driving the system somewhat above its natural frequency, that is, under conditions of inertial load. The compliance of the system was such that the shortening during one cycle was only 0·1 mm., or 0·3 per cent of the length of the fibre. Thus if the feedback mechanism works through length (rather than tension), only a small change is required.

The interest of this phenomenon would appear to be twofold. First, it closely resembles the situation in the flight muscles of insects, studied by Pringle[2] and Boettiger and Furshpan[3]. Secondly, it supports the hypothesis of a direct action of lengthening on activation in muscle, which has been proposed[4] as a result of a study of activation[5] in intact muscle, where it is shown that auto-oscillations can then occur only with an inertial load. In this connexion the latency relaxation of Sandow[6] was considered to be an expression of essentially the same mechanism.

Auto-oscillations with another phosphate donor system have been found by Lorand and Moos (personal communication; see following communication), whose extraction procedure is also effective with the creatine phosphate system.

[5] Goodall, M. C., *J. Gen. Physiol.* (in the press).
[6] Sandow, A., *Ann. N.Y. Acad. Sci.*, **47**, 895 (1947).

In connexion with our studies on the relaxing effect of the pyruvate phosphokinase system[1], the following procedure was used for preparing the muscle fibres. Rabbit psoas is washed in 50 per cent (v/v) aqueous glycerol (as in the original treatment of Szent-Györgyi[2]) for two days at 0° C., then stripped into bundles of approximately $\frac{1}{4}$ mm. diameter and shaken at room temperature (about 25° C.) in 20 per cent (v/v) glycerol for various lengths of time. After one to two hours extraction, the fibres develop maximal isometric tension in a bath consisting of 0·1 *M* potassium chloride, 4 m*M* magnesium chloride, and 4 m*M* adenosine triphosphate, and there is no sign of spontaneous relaxation. However, addition of 10 m*M* phosphoenolpyruvate brings about immediate relaxation. Further details on the relaxation with phosphoenolpyruvate will be published elsewhere; here, we wish to report on the results obtained by extracting psoas fibres in 20 per cent (v/v) glycerol for at least 24 hr. If such an exhaustively washed fibre is placed in a bath containing the above concentrations of potassium and magnesium chlorides and adenosine triphosphate, maximal tension develops, and upon the addition of phosphoenolpyruvate a spontaneous oscillation occurs as shown in Fig. 1.

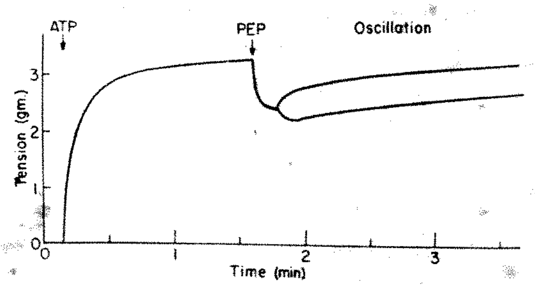

Fig. 1. Oscillating response of glycerinated psoas fibre in the presence of 0·1 *M* potassium chloride and 4 m*M* magnesium chloride. Bath at *p*H 7. ATP = addition of 4 m*M* final concentration of adenosine triphosphate. PEP = addition of 10 m*M* final concentration of phosphoenolpyruvate. Oscillation frequency, 2·8 c./s. Details are not resolved by slow kymograph drum. Double line represents envelope of oscillation

Phosphoenolpyruvate seems to be essential for maintaining the oscillation, as it stops if the fibre is transferred to a bath containing only potassium and magnesium chloride and adenosine triphosphate, but it starts anew in a bath having phosphoenolpyruvate as well. The frequency of oscillation is about 2·5–3 c./s., which in our case coincides approximately with the resonant frequency of the recording lever system loaded with the muscle fibre. In a batch of fibres washed in 20 per cent (v/v) glycerol for 24 hr., usually about 25 per cent of the fibres display the oscillating behaviour. An apparently identical phenomenon has been observed by Goodall (personal communication; see previous communication), who employed creatine phosphate instead of phosphoenolpyruvate.

By dialysing and freeze-drying the 20 per cent (v/v) glycerol solution used for the 24-hr. extraction of the muscle fibres, a preparation is obtained which stops the oscillations very effectively when added to the bath. Oscillations are resumed, however, if the fibre is transferred to a fresh bath without the muscle extract. An equally active preparation for stopping oscillations may be obtained by extracting freshly homogenized rabbit muscle with an equal volume of 0·15 *M* potassium chloride. The active factor (or factors ?) for inhibiting oscillation is non-dialysable and thermolabile.

This oscillation of glycerinated fibres is very reminiscent of the behaviour of the bumble bee wing muscle[3]. Indeed, one wonders if the oscillation observed in the insect muscles might not be due to the absence of a 'damping factor' similar to that shown here to exist in the rabbit psoas.

Plasma Factor(s) influencing Red Cell Production

There is an accumulating body of evidence of the existence of a humoral substance(s) in the plasma of animals with induced anæmia which stimulates erythropoiesis in recipients[1].

We have found that when young adult rats are hypophysectomized by a standard technique (from Hormone Assay Laboratories, Inc., Chicago), erythropoiesis is reduced to a minimum by 10–14 days after the operation as shown by a tenfold reduction in the incorporation of iron-59 into the red cells and by a fivefold reduction in the number of reticulocytes. When this level of erythrocyte production is reached, the administration of plasma (2 ml. daily for three days) from rats made anæmic by repeated bleeding (anæmic plasma) results in a three- to seven-fold increase in the amount of iron-59 taken up by the erythrocytes (Table 1) and in a three- to eight-fold increase in the number of reticulocytes in the recipients. As previously described[2], the iron-59 solution is injected through the tail vein 2 hr. after the last plasma injection; 16 hr. later, a 1-ml. sample of blood is withdrawn from each rat and the radioactivity is counted in a well-type scintillation counter. No significant change is observed in the incorporation of iron-59 into the red cells of the control hypophysectomized rats given normal plasma or saline under these experimental conditions. The blood volume and red-cell mass of hypophysectomized rats, as determined by chromium-51 studies, remain within normal limits during this initial two-week period. A single intravenous or intraperitoneal injection of 2 ml. of anæmic plasma given 24 hr. before the injection of iron-59 elicits a significant increase in the incorporation of iron-59 into the red cells of hypophysectomized rats. Two injections of 2 ml. each of anæmic plasma from other species (for example, rabbit, dog or human being) evoke a positive erythropoietic response in the hypophysectomized rat. Six or more daily 2-ml. injections of normal rat plasma must be given to produce a definite increase in iron-59 taken up by the red cells of hypophysectomized recipients.

The plasma from hypophysectomized rats subjected to hæmorrhage (hæmatocrit less than 25 per cent) exerts an effect on the uptake of iron-59 in hypophysectomized rats that is comparable with that observed after the administration of anæmic plasma.

At this stage of our investigations we prefer not to debate the question raised by others as to whether there is a specific pituitary factor that has a direct control on erythropoiesis; but it is an established fact that the red-cell mass falls slowly to a new equilibrium-level within a period of two to three months after hypophysectomy[3].

The simplest explanation for our findings may be summarized as follows: Within a few days after hypophysectomy, an overall reduction occurs in the metabolic processes of the animal. With the reduced metabolic requirement and before the red-cell mass has fallen to its new level of equilibrium, the hypophysectomized animal is more or less comparable to an animal that has been made polycythæmic by red-cell transfusion. It may be postulated that, in these circumstances, the production of the plasma factor(s) responsible for maintenance of the steady state of circulating erythrocytes is reduced to a minimum since a plethora of red cells already exists. Thus, there is a situation that in essence is the reverse of that which obtains when a normal animal is bled. As a consequence, red-cell production is reduced to a minimum. When anæmic plasma is administered under these conditions, there is an exaggerated response in terms of the production of new red cells. As final and complete equilibration of red-cell production and the new reduced red-cell mass slowly become established in the hypophysectomized animal, one finds, as would be expected, that the number of reticulocytes and the uptake of iron-59 have risen from the low values found shortly after hypophysectomy to values that are consistent with the new steady state. As reported by others[4], we have found that producing a polycythæmia in normal animals (mice, rat, rabbit) by repeated transfusion of red cells reduces erythrocyte production. The response to anæmic plasma in these polycythæmic animals in terms of the incorporation of iron-59 into the red cells or the increase in reticulocyte values is comparable with that observed in hypophysectomized animals.

Table 1. Uptake of Iron-59 by Erythrocytes of Hypophysectomized Rats after Administration of Normal or Anæmic Plasma

Average percentage iron-59 uptake into red-blood cells of rats*				
Plasma injected	No. of animals	Prior to hypophysectomy	No. of animals	10 days post-hypophysectomy
Normal	8	37	17	3·7 ± 2†
Anæmic	5	48	16	20·4 ± 6†

* 16-hr. sample. † Standard deviation of the mean.

Note: While the number of animals prior to hypophysectomy is small, the results are in excellent agreement with those reported on a large number of rats (see ref. 2) when the sampling time was 20 hr.

We assume for the sake of simplicity that the factors in normal plasma and in the plasma of normal or hypophysectomized animals subjected to bleeding that stimulate erythropoiesis in hypophysectomized and in polycythæmic assay preparations are one and the same. Further study may, however, reveal a somewhat more complicated picture. Nevertheless, with this sensitive assay method, it should be possible to make more rapid progress in determining the source, the identity, and the physiological role of the plasma factor(s) under discussion in conditions of health and disease. Our studies will be published in detail elsewhere.

Embryology, Epigenetics and Biogenetics

In his stimulating review of Prof. C. H. Waddington's "Principles of Embryology", Dr. Julian Huxley[1] expresses the hope that Prof. Waddington will write a sequel, and, following his earlier impulse, call it "Principles of Epigenetics". While the term 'embryology' suggests a field far more restricted than that which this department of science is now concerned with, the suggested alternative, 'epigenetics', has disadvantages of another kind. It still reverberates with the overtones of a *cause célèbre*, a controversy in which, as it now appears, neither 'epigenesis' nor 'preformation' gained a decisive victory. For whereas identifiable organized units, whether organs or tissues, appear successively from an apparently undifferentiated mass, there is now no question but that the material determinants of these new structures are preformed in the chromosomes recognizable before the beginning of embryonic life. That this caution is not a matter of mere historical pedantry is evidenced by the fact that another worker of long experience in this field, M. Jean Rostand, has recently[2] referred to the "extravagances du préformationnisme" and the "naïvetés de l'épigenèse".

In another place[3] I made the suggestion that the whole field comprising the problems of the 'genesis' of organisms could appropriately be styled as 'biogenetics', with subdivisions, 'ontogenetics' (the development of individual organisms), 'phylogenetics' (theories of descent) and 'stoichiogenetics' (quantitative 'genetics' *sensu strictu*), thus bringing out the unitary character of the field. It seems highly regrettable that no one was looking when those responsible for launching the new discipline concerned with the sub-field of the relation between adult 'characters' and transmitted determinants arrogated to it the higher-level name of 'genetics'. Whence my suggestion that, despite the high authority of the sponsors of the term 'epigenetics', the latter should not be too hastily accepted.

[1] Huxley, *Nature*, **177**, 807 (1956).
[2] Rostand, *J. World Hist.*, **2**, 134 (1954).
[3] Wightman, *J. World Hist.*, **2**, 734 (1955).

THE fact that the word 'epigenetics' is reminiscent of 'epigenesis' is to my mind one of the points in its favour. As Dr. Wightman points out, in the old controversy, now stilled, between the theories of epigenesis and preformationism, neither side emerged completely victorious. We all realize that, by the time development begins, the zygote contains certain 'preformed' characters, but that these must interact with one another, in processes of 'epigenesis', before the adult condition is attained. The study of the 'preformed' characters nowadays belongs to the discipline known as genetics; the name 'epigenetics' is suggested for the study of those processes which constitute the epigenesis which is also involved in development. Admittedly the word 'genetics', which was coined by Bateson to cover "the physiology of descent", might have been used so as to embrace both aspects of development; but in practice it has not been widely employed in that sense.

Incidentally, it was not entirely from diffidence, as Huxley suggested, that I named my book the "Principles of Embryology"; I did so mainly because it devotes some space to the descriptive anatomical data relating to development, and is not confined wholly to that analysis of causal mechanisms for which the name 'epigenetics' is appropriate.

Effect of Some White Pigments on the Actinic Degradation of Cotton

THE action of solar radiation in reducing the strength of cotton is well known. In our experience, 12-oz. grey cotton duck exposed to weather in a non-industrial atmosphere near Melbourne, Victoria, loses about 25 per cent of its strength in twelve months, due solely to the action of light. Although fungal growth is commonly observed on exposed cotton fabrics, the species isolated have always been non-cellulolytic; fibres from exposed fabrics when examined microscopically by the modified congo red test[1] show actinic damage but no fungal damage.

The rotproofing treatments customarily applied in Australia to cotton duck intended for use in tentage are based on copper compounds all of which accelerate actinic action[2]. Fabrics treated with copper soaps and cuprammonium solutions may lose 70–80 per cent of their strength during twelve months exposure; copper naphthenate and copper 8-quinolinolate are less severe in their effects, but fabrics treated with them lose 40–50 per cent of their strength in that time. To reduce the effects of the copper compounds, Australian rotproofed tentage fabrics are given a protective pigment coating. Iron and chromium pigments have generally been used; but there is some demand for a white as well as a coloured finish. Zinc oxide has been tried; but it is difficult to incorporate in the coating emulsions used and it gives a grey colour rather than white. Other white pigments are easily incorporated in synthetic resin emulsions, and limited trials were arranged to determine the effect of the pigments that could be used in this way, the pigments being used singly or in mixtures.

The pigments were incorporated in synthetic resin emulsions and the various emulsions applied to 12-oz. grey cotton duck. The treated fabrics were exposed for twelve months (June 1954–May 1955) at Reservoir, near Melbourne, in a non-industrial atmosphere.

Table 1

Pigment used in emulsion	Chemical analysis of unexposed fabrics				Loss of strength after 12 months exposure (per cent)
	$BaSO_4$ (per cent)	ZnS (per cent)	TiO_2 (per cent)	Other (per cent)	
Series I					
Lithopone (30 per cent)	2·4	1·1	—	—	29
Lithopone (60 per cent)	1·2	1·1	—	—	38
Anatase	—	—	2·8	—	93
Rutile *A*	—	—	3·6	—	2
Antimony oxide	—	—	—	Sb_2O_3: 3·8	24
White lead	—	—	—	Pb: 2·8	26
Zinc sulphide	—	3·5	—	—	38
Series II					
Lithopone (60 per cent)	1·3	1·2	—	—	29
Lithopone and anatase	1·0	0·8	0·2	—	68
Lithopone and anatase	0·6	0·6	0·8	—	81
Anatase	—	—	3·3	—	87
Lithopone and rutile *A*	1·4	1·2	0·2	—	31
Lithopone and rutile *A*	0·8	0·6	0·8	—	15
Rutile *A*	—	—	3·2	—	5
Lithopone and rutile *B*	1·2	1·1	0·2	—	20
Lithopone and rutile *B*	0·7	0·7	0·8	—	14
Rutile *B*	—	—	3·4	—	4
Untreated	—	—	—	—	27

The pigments used, the results of chemical analyses of the unexposed fabrics, and the losses of breaking strength after exposure, are set out in Table 1.

The effect of anatase is startling. Fabrics containing about 3 per cent of this pigment lost 90 per cent in strength. Lithopone alone has only a slight effect on the loss of strength, but when small amounts of anatase are added the loss of strength is greatly increased. On the other hand, the presence of rutile retards the loss of strength. The other pigments used have little or no effect.

Fibres from the exposed materials examined by the congo red test showed varying degrees of actinic degradation but no damage from other causes. The intensity of the staining of the fibres increased with increasing loss of strength. The fabrics containing rutile showed only the faintest signs of actinic action; but all the fabrics containing anatase showed severe actinic damage.

These results indicate that anatase accelerates the actinic degradation of cotton and that rutile has a protective effect. The effect of anatase on cotton is consistent with its effect on fibres such as nylon and 'Perlon'. We have recently examined some deteriorated fabrics made from these fibres in which anatase had been used as a delustrant. Exposure of the fabrics to sunlight for a short time (about three months) had produced great losses of strength; this effect does not occur with bright (undelustred) nylon. The different effects of anatase and rutile in paints exposed to weather are well known[3]; paints containing anatase chalk rapidly and heavily, but paints containing rutile chalk only very slowly. We suggest that this may be due to the different reactions of the two pigments to light, and may be similar to the differences observed in Australia between chalking and non-chalking grades of zinc oxide[4]. The generally accepted explanation of the different effects is based on deficiencies in the spatial arrangement of the oxygen atoms in the crystal, whereby anatase can be reduced in the presence of oxidizable compounds; light provides the necessary stimulus for the reduction and atomic oxygen is liberated and attacks the oxidizable material. Cellulose can be readily oxidized with accompanying loss of strength, and it appears that the accelerating effect of anatase on the actinic degradation of cotton could be explained in the same way.

A Gas Phase in Viable Fungal Spores

WHEN the dark ascospore of *Sordaria fimicola* is examined dry, a round paler zone in the middle is invariably seen. If the spore is flooded with water, it is clear that this zone is a gas bubble which disappears in a few minutes. If the spore is again allowed to dry, very shortly after the last visible trace of external water has disappeared, a tiny intracellular gas bubble 2–3μ in diameter suddenly appears and rapidly enlarges. With further drying, as well as the enlargement of the bubble, the spore itself caves in to some extent. The separation of a gas phase seems to be an invariable concomitant of drying. It is easy to show that dry spores containing gas bubbles are fully capable of germination when placed in a suitable solution.

Exactly the same behaviour has been seen in ascospores of *Pleurage curvicolla* (Fig. 1) and *Hypoxylon fuscum*.

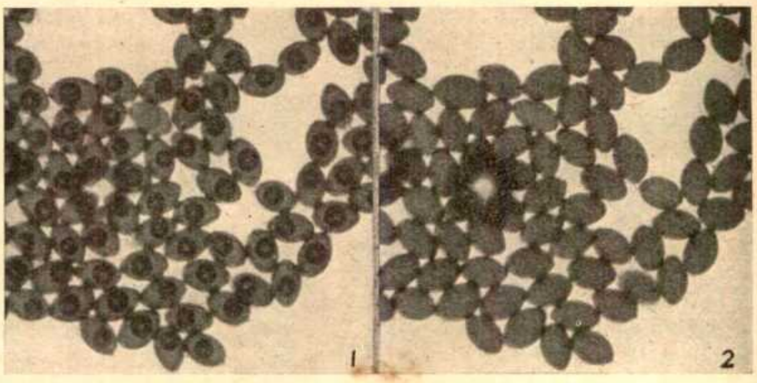

Fig. 1. (1) Freshly discharged spores of *Pleurage curvicolla* caught on a dry slide and photographed 15–20 sec. after flooding with water; each contains a gas-bubble. (2) The same spores 60 sec. later; the gas phase has disappeared. × 420

It seems likely that the gas bubble originates within the spore just as it does during spore discharge in the annulus cell of a drying fern sporangium or in the elater of a leafy liverwort. That is to say, as evaporation proceeds, the volume of the spore tends to be reduced; but this reduction is resisted by the rigidity of the cell wall, so that the aqueous contents pass into a state of tension which increases until a point is reached when rupture occurs and a gas phase, presumably water vapour, suddenly appears. That the bubble is water vapour is supported by the fact of its rapid disappearance when the spore is placed in water.

The gas phase can also be produced in *Sordaria* spores by dehydrating with glycerol. This can easily be observed if a small drop of water containing spores on a microscope slide is mixed with a larger drop of pure glycerol. A gas phase separates in most of the spores, although some simply collapse.

The sudden separation of a gas bubble on drying might be expected to produce a movement of the whole spore; but no such movement is seen in *Sordaria*, possibly because the spore is so firmly glued to the microscope slide by its sheath of mucilage.

There does not seem to be any biological significance in the occurrence of a gas phase in ascospores. If, however, the separation of gas in plant cells without loss of viability is at all general, it may be important. Thus, if a gas phase were suddenly to appear on drying in a spore finely perched on a conidiophore, the jolt night well be enough to discharge it into the air. Possibly the temporary appearance of gas in living lant cells with rather rigid walls may be of common ccurrence; in hard-leaved xerophytes, for example. However, since the gas would very quickly disappear n sections mounted in water, it would not normally be observed.

So far as I know, the pseudovacuoles of some blue-reen algae are the only previously recorded examples f a gas phase in living plant cells.

Septate Fibres in Angiosperms and their Length

Recently, Govindarajalu and Swamy[1] have reported that the septate fibres are longer than the non-septate fibres in the secondary xylem of *Pithecolobium dulce* Benth. Since this is the first record of the difference between the length of septate and non-septate fibres in a wood, one is likely to get the impression that what has been found in *P. dulce* is true for all the Dicotyledons; but this is not so. In the course of our investigation, during the past five years, on septate fibres of Angiosperms, we find that in a large number of species there is little difference in length of these two types of fibres. Only in a few cases are septate fibres found to be either shorter or longer than non-septate fibres (Table 1).

Table 1. Length of Septate and Non-septate Fibres in Angiosperms

Family	Species	Mean length in mm.* Septate fibres	Non-septate fibres
Anacardiaceae	*Dracontomelum mangiferum* Blume	1·32	1·34
Bignoniaceae	*Heterophragma sulfureum* Kurz	1·22	1·23
Celastraceae	*Celastrus spinosa* Royle	0·54	0·73
Combretaceae	*Terminalia tomentosa* W. and A.	1·37	1·36
Elaeocarpaceae	*Elaeocarpus serratus* Linn.	1·53	1·47
	Elaeocarpus simplex Kurz	1·40	1·49
Lauraceae	*Cinnamomum glanduliferum* Meissn.	1·34	1·50
	Machilus fruticosa Kurz	1·33	1·58
Leguminosae	*Albizzia lebbeck* (L.) Benth.	1·17	1·19
	Peltophorum ferrugineum Benth.	1·16	1·10
	Pithecellobium dulce Bth. (Syn. *Pithecolobium dulce* Benth.)	0·80	0·55
	Samanea saman (Jacq.) Merr.	1·22	1·19

Oleaceae	*Ligustrum compactum* Hook. f. and Th.	0·89	0·92
Punicaceae	*Punica granatum* Linn.	0·57	0·57

* Based on more than 150 measurements.

In *Dendrocalamus strictus* Nees of the Gramineae, septate fibres occur both in the xylem and the phloem caps. Preliminary examination shows considerable difference between the length of septate and non-septate fibres found in the vascular bundles of the periphery and those of the interior (Fig. 1). Towards the interior the septate fibres are shorter than the non-septate fibres, whereas in the periphery they are longer.

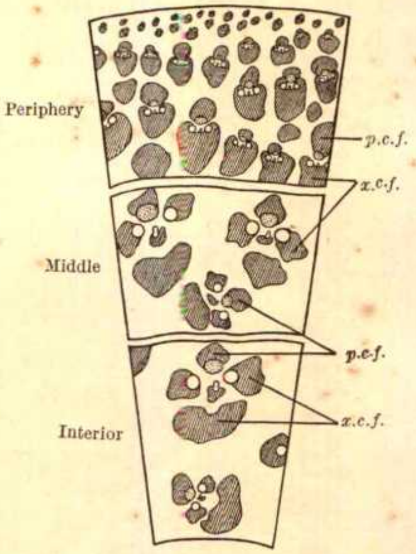

Fig. 1. *Dendrocalamus strictus* Nees, transverse section, internode, in part; *p.c.f.*, phloem cap fibres; *x.c.f.*, xylem cap fibres (× 15, diagrammatic)

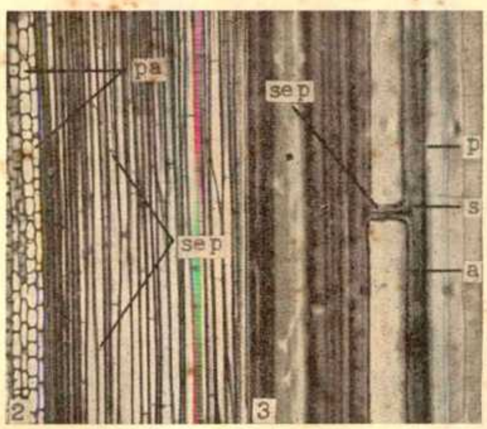
Vestal and Vestal[2] first demonstrated the development of septate fibres in *Hypericum androsaemum* Linn. Purkayastha has worked out the development of septate fibres in some tropical trees. In the course of his investigation he has found that some crystalliferous fibres are related to septate fibres[3]. Again, Chowdhury has reported that in some genera there is little effect of environment on the frequency of occurrence of septate fibres, whereas in others, formation of septate fibres varies from locality to locality[4]. Recently, our work on bamboo (*Dendrocalamus strictus* Nees) has shown that the protoplasts in these fibres mostly live for a long time, often even after laying down the secondary wall (Fig. 2). Occasionally an additional layer is also deposited both on the vertical wall as well as on the septum. As a result, the septum is quite thick and consists of three distinct layers (Fig. 3).

The function of the septate fibres is at present not clearly understood. To say that the special function



D. strictus Nees, longitudinal section, internode. Fig. 2. *pa*, parenchyma; *sep*, septa (× 60). Fig. 3. *p*, primary wall; *s*, secondary wall; *a*, additional layer; *sep*, septum (× 500) of the septate fibre is to give mechanical strength and serve for storage of food material is not quite correct[5]. In tropical woods, non-septate and septate fibres, and even vessels, have been observed to serve as storage tissues in living trees (Chowdhury, K. A., unpublished work).

A detailed account of this investigation will be published elsewhere.

Effect of Hormone Herbicides on the Growth of *Rhizobium trifolii*

IN view of the widespread use of hormone-type herbicides on mixed stands of crop plants containing clover as an essential constituent, it would appear to be of considerable importance to determine the effect of these substances on the growth of the clover nodule-forming organism. This is particularly true of the phenoxybutyric compounds which have been recommended for use as herbicides where clover is present, since they have been shown by Wain[1] and other workers to have no harmful effect on clover due to the latter's lack of the β-oxidizing enzyme system.

The substances investigated in this experiment were the sodium salts of 24*D* (2 : 4-dichlorophenoxyacetic acid), *M.C.P.A.* (2-methyl-4-chlorophenoxyacetic acid), 245*T* (2 : 4 : 5-trichlorophenoxyacetic acid), 24*DB* (γ-(2 : 4-dichlorophenoxy)butyric acid), and *M.C.P.B.* (γ-(2 methyl-4-chlorophenoxy)butyric acid). They were incorporated in a yeast–mannitol agar[2] in the appropriate concentration of acid equivalent. Two agar plates were prepared for each concentration. A standard suspension of a known effective strain of rhizobium (*Rh. trifolii* 157) was prepared in sterile distilled water and three loopfuls were streaked on each Petri dish of agar. The plates were incubated at 24° C. for four days.

From the results it is clear that the herbicides had no effect on the growth of *Rhizobium trifolii* at concentrations up to 25 p.p.m. Beyond this level, the growth was moderate to poor up to 500 p.p.m. The bacteriostatic point lies beyond 500 p.p.m. but has not yet been determined. It will be noted that the butyric-acid compounds 24*DB* and *M.C.P.B.* were slightly less toxic than the acetic-acid compounds 24*D*, *M.C.P.A.*, and 245*T*.

Table 1

Substance / Conc. p.p.m.*	24*D*	*M.C.P.A.*	245*T*	*M.C.P.B.*	24*DB*
0	+++	+++	+++	+++	+++

5·0	+++	+++	+++	+++	+++
25·0	+++	+++	+++	+++	+++
50·0	++	++	++	+++	++
100·0	+	+	+	++	++
200·0	+	+	+	++	++
300·0	+	+	+	+	+
400·0	+	+	+	+	+
500·0	+	+	+	+	+

* Acid equivalent. + poor growth; ++ moderate growth; +++ good growth.

Relating these figures to soil conditions, 1 acre of topsoil to 8–9 in. depth contains approximately 3 million pounds of moist soil. This refers to 'mineral' soil with about 3–12 per cent of organic matter. A convenient figure for the weight of topsoil of an arable field to the deliberately vague specification of 'plough depth' would be 2¼ million pounds or 1,000 tons. If the actual content of active growth substance in an application, on reaching the soil, is as much as 1 lb., the momentary concentration in the topsoil (assuming even distribution) is 0·5 p.p.m. approximately.

These are the concentrations over the whole mass of soil. But the substance is effective against plants or microbes only to the extent that it dissolves in the soil water. Assuming no adsorption but complete solution, and a 20 per cent water content of soil, the concentrations become 2–2·5 p.p.m. = 1 lb./acre approximately. Since the growth of *Rhizobium trifolii* is unaffected by concentrations up to 25 p.p.m. (= 10 lb./acre), it can be assumed that the concentrations used in agricultural practice (usually 1 lb. of the acid equivalent per acre) will have no adverse effect on the growth of *Rhizobium trifolii* even assuming that all of it reaches the soil.

Thanks are due to Messrs. May and Baker, Ltd., for supplying the *M.C.P.B.* and 24*DB* for experimental purposes.

Growth of Lettuce Seedlings

THE methods of growth analysis[1] have been applied to comparatively few horticultural crops; yet, as stated by Gregory at the Thirteenth International Horticultural Congress in 1952 [2], these techniques open up a wide field in horticultural research and are an essential basis of any attempt to understand the control of growth by environmental factors.

The following results were obtained with lettuce (*Lactuca sativa*, Linn.), variety Cheshunt 5*b*, during the course of an investigation of the rate of recovery of seedlings from the check of transplanting, full results of which will be reported elsewhere. The study was confined to the first three or four weeks of growth; that is, up to or beyond the normal stage for planting out. Plants were raised at various seasons in growth rooms and also during mid-winter in a heated glasshouse. In the growth rooms, plants were grown at constant temperatures of 70°, 60° and 50° F., day-lengths of 16 and 9 hr., and light intensities, at plant-level, of approximately 650, 400 and 250 ft. candles, using fluorescent daylight tubes. Net assimilation-rates were obtained by the usual formula[3], leaf areas being calculated from length and breadth measurements, excluding the petiole. Good

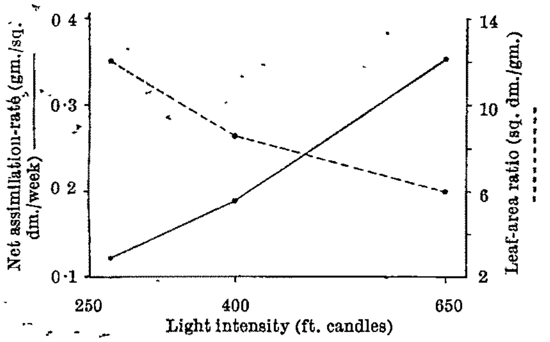

Fig. 1. Temperature, 70° F.; day-length, 16 hr.; period, 14–23 days from germination

correlation was obtained between actual leaf area and the products of length and breadth measurements when determined in small samples.

Net assimilation-rate varied with environmental conditions, values ranging from 0·06 gm. per sq. dm. per week, under natural light in a glasshouse in mid-winter (temperature-range 50–60° F.), to 0·35 at 70° F. with 16-hr. days and a light intensity of approximately 650 ft. candles. As found by Blackman and Wilson for several species[4], net assimilation-rate increased with light-intensity over the range tested (Fig. 1). Higher net assimilation-rates were recorded in long than in short days; but a negative relationship was indicated between temperature and net assimilation-rate (Table 1).

Table 1

Day-length: 16 hr. Light-intensity: 400 ft. candles

	70° F.	60° F.	50° F.	S.E.
Mean net assimilation-rate during first four weeks of growth	0·145	0·174	0·197	± 0·0077

Leaf area ratios, on the other hand, were significantly increased at higher temperatures, but decreased at higher light-intensities. Fig. 1 illustrates the relationship between light intensity, net assimilation-rate and leaf-area ratio, and effects of temperature and light-intensity on leaf-area ratio are shown in Table 2.

Table 2

Day-length: 16 hr 14–23 days from germination

Temperature (° F.)	Light intensity (ft. candles)	Leaf-area ratio (sq.dm./gm.)
70	650	6
50	400	6
70	400	9
70	250	12

Abundant water was made available to all plants by means of a system of constant sub-irrigation. Conditions of high temperature and low light-intensity, which induced high leaf-area ratios and low net assimilation-rates, were accompanied by increased moisture content, as shown by the ratios of wet to dry weights.

Relative growth-rate is the product of net assimilation-rate and leaf-area ratio. Plants grown at the lowest light-intensity had a low net assimilation-rate, but a high leaf-area ratio which, to some extent, had a compensatory effect on relative growth-rate. Values of relative growth-rate ranged from 0·09 to 0·32 gm. per gm. dry weight per day, and it is believed that the latter is the most rapid rate of growth recorded for a crop plant. Rapid growth-rates do not necessarily produce the best type of plant, since this is dependent on a suitable balance between leaf-area ratio and net assimilation-rate. For example, plants with high leaf-area ratios had long petioles and the leaves were thin and soft in texture.

These results emphasize the importance of maintaining a suitable balance between temperature and light-intensity for satisfactory growth. This applies particularly to the culture of plants in glasshouses during winter, when light-intensity is low and where high temperatures cannot compensate for lack of light.

Growth analysis provides a means of examining and evaluating the effects of horticultural practices. The present investigation has clearly shown that severe reduction of the root or shoot during transplanting at the cotyledon stage checks growth, but that the effect is temporary. Under good growing conditions, the shoot/root ratio, net assimilation-rate, leaf-area ratio and relative growth-rate rapidly reassume values comparable with those of an uninjured plant. Lettuce seedlings showed considerable modification in their habit of growth under the conditions to which they were subjected in these experiments.

Soil Thermometers

FOR the measurement of soil temperatures at depths of 1 ft. or greater, it is established practice in many parts of the world to use a specially modified thermometer which is hung in a tube and withdrawn for reading. So that its indication will not change appreciably during the process of reading, the bulb is surrounded by a mass of paraffin wax to give it a high lag coefficient.

We have recently had occasion to check the calibration of a number of these thermometers and found that at 40° F. and below their indications were considerably in error. At 40° F., errors of between 1° and 2° F. were not uncommon, and at 20° F. the errors might be as large as 6° or even 8° F. In all cases the thermometers were reading high. The thermometers themselves, when removed from the wax, had negligible errors, that is, they were within the limits of accuracy laid down for this class of thermometer.

When the thermometers were subjected to an external hydrostatic pressure of several hundred pounds per square inch, the bulbs were reversibly deformed sufficiently to cause errors of the above magnitude. It is clear from this, and other tests, that the errors are caused by pressures developed on the bulbs by thermal contraction of the wax at low temperatures. The errors so caused are not repeatable and depend on the previous thermal history of the thermometer, presumably because of plastic flow in the wax.

Only thermometers of one maker have been checked; but since the trouble is due to a fundamental weakness in the design specification, the products of other makers using similar waxes will presumably be affected to a greater or lesser degree.

In view of the fact that thermometers of this design are fairly widely used, it was thought desirable to bring the situation to the notice of as wide a group of interested people as possible: particularly those interested in using these instruments for studying long-term trends in earth temperature.

Periodicity of the Laminariaceae around Scotland

During 1946–55, an extensive survey of the Laminariaceae growing around the coast of Scotland has been in continuous operation. The whole of the marine coast of Scotland—more than 6,000 miles—has been photographed (through the co-operation of the Royal Air Force) and, with the aid of these stereoscopic aerial photographs, quantitative assessments of the Laminariaceae have been made by using ecological factors which the data, collected from detailed sub-littoral surveys, have revealed[1].

Detailed surveying, using methods of quadrat sampling with calibrated spring grabs[2], was operated from boats on charter from the fishing fleet, during all times of the year.

Over sub-littoral areas of the north-east, north-west, south-east and south-west mainland of Scotland, the Orkney Islands and the Isle of Skye, eighty-six detailed surveys have been completed and analysed, and of these more than half have been re-surveys (for example, Girvan to Bennane, six times). This work has involved the measurement of 100,000 quadrats from more than 67,000 acres (27,000 hectares) of the sea bed.

It has been found that changes in the quantity as well as the ratio of species occurred over a number of years; it is now possible to indicate the trend. By far the greater quantity of the Laminariaceae was found above five fathoms (nine metres) and consisted of *Laminaria cloustoni* Edm., *L. saccharina* Lamour and *L. digitata* Lamour. Based on all quadrat values obtained from eighty-six surveys, mean fresh weight per unit area of the three Laminariae, found between one and five fathoms, in each calendar year, from 1946 until 1955, was:

	lb./sq. yard (× 0·54 for kgm./sq. metre)		lb./sq. yard (× 0·54 for kgm./sq. metre)
1946	9·1	1951	5·4
1947	13·4	1952	3·7
1948	11·2	1953	2·8
1949	8·0	1954	3·4
1950	5·0	1955	4·7

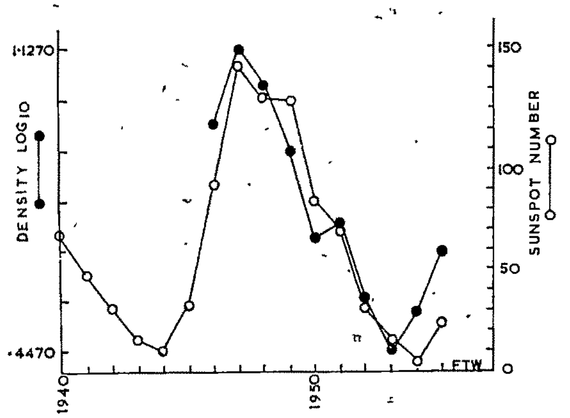

Fig. 1. Relationship of the fresh weight of Laminariaceae and the frequency of sunspots

These values when plotted logarithmically show the trend over the past ten years (Fig. 1).

Extrapolation of the graph backwards in time gives a trough in 1942 of the same level as 1953; and forwards in time gives a crest in 1958 of the same level as 1947. Ecological factors combining to produce an eleven-year cycle would appear to be controlling the reproduction, colonization and growth of the Laminariaceae around Scotland.

Mention of an eleven-year cycle brings to mind sunspot activity. The annual mean of monthly sunspot numbers, published by the Federal Observatory, Zurich, have also been plotted in Fig. 1. The Royal Greenwich Observatory finds there is a satisfactory parallelism between these mean sunspot numbers and the sunspot areas which they measure. It will be seen that the two graphs show a surprising degree of correlation.

The laminarian periodicity is not thought to be the direct consequence of sunspot activity, but rather the indirect result of such activity producing meteorological conditions which in turn are reflected in the marine environment.

I wish to thank Mr. W. H. Newton, of the Royal Greenwich Observatory, for supplying the information on sunspot activity.

A Marlin in Angola, with a Note on *Makaira herschelii* (Gray), 1838

Marlin fishes of the genus *Makaira* Lacépède, 1801, in which the dorsal fin is lower than the body, are found over wide areas of the three main oceans in a broad equatorial belt, mostly within the 20° isotherms. In the Atlantic proper there has so far been found only the so-called 'blue' marlin, generally named *Makaira ampla* (Poey), 1860. This fish, doubtfully distinct by full specific rank from the Indo-Pacific 'black' marlin, *M. herschelii* (Gray), 1838, is said to occur also in the Pacific. In the Atlantic the blue marlin has been recorded in scientific literature chiefly from the region of the West Indies, and from the north-western coastal areas of South America. It has also been reported from off south-western Europe, and from St. Helena (lat. 16° S., long. 5° 40′ W.) in the south Atlantic. The other smaller marlin of the Atlantic, and confined to that ocean, *Lamontella*[1] *albida* (Poey), 1860, has a somewhat similar but less extensive distribution than *M. ampla*, while the 'mystery' marlin, *Orthocraeros*[1] *bermudae* (Mowbray), 1931, is known from only one specimen, photographed but regrettably destroyed.

As marlins are known to travel widely, it is astonishing to find that the range of these fishes in the Atlantic is far more restricted than might be supposed. Up to the present, there has not appeared in scientific literature any report of the occurrence of any species of marlin anywhere near the whole length of the extensive western coast of Africa. Colonel J. K. Howard, of Miami, has informed me privately that he caught a marlin (unspecified) at Cape Verde, and that natives told him that marlins had been seen off Accra, Gold Coast (4° N.); but no confirmatory evidence is available.

What is remarkable is that I cannot find any evidence of a single marlin of any kind having ever been reported from a vast area of the Atlantic, extending north-west from the Cape, bordered on the east by the west coast of Africa, and including the enormous area of the Gulf of Guinea. This is certainly an astonishing gap, for it is an area with notable concentrations of the comparable tunny fishes, where marlins might well be expected to occur and even to abound.

Partly as a result of the publicity attending recent marlin discoveries in South African seas, a considerable amount of interesting information has reached me. One item is a photograph of a large marlin thrown ashore at Lobito Bay, Angola (lat. 12° 30′ S., long. 13° 10′ E.). The fish had been damaged by sharks and from the photograph was patently putrescent; but it certainly falls in *Makaira* Lacépède, and is thus the first marlin ever to be reported in the eastern Atlantic area defined above. No dimensions of any kind were apparently taken of the fish itself, but the photograph contains sufficient detail to enable the principal dimensions to be estimated, and by careful compilation and deduction these would have been very close to the following: total length, 144 in.; standard length, 124 in.; depth of body, 22 in.; height of dorsal lobe, 17 in.; suprapectoral height, 17 in.; length of head, 42 in.; spear before eye, 28 in.; tip of spear to tip of lower jaw, 15 in.; estimated weight, about 450 lb.

This information alone does not clearly settle the identity of the fish as a 'black' or a 'blue' marlin, though the relatively elevated dorsal lobe indicates 'blue'. On the other hand, that fin in this case falls within the upper limit recorded for the 'black', while the relatively short stout spear is more characteristic of the latter fish.

The discovery of this fish at Lobito opens up several interesting possibilities. It may have been a black marlin, the presence of which in the Atlantic I have long suspected. Also this Lobito fish does not necessarily indicate that marlin are abundant along the west coast of Africa, for no others have been reported there and this may have been a stray. On the other hand, anglers in Angolan waters not infrequently have strong tackle ripped away by unknown monsters that might well be marlin, and careful search may reveal that they are normally present there.

The third undoubted marlin to be reported in scientific literature was *Tetrapturus herschelii* (Gray), 1838, based on an 11-ft. fish thrown up in Table Bay. Some American workers have suggested that *herschelii* was of Atlantic origin and hence of uncertain identity in relation to its position as the first valid type of the black marlin, which most name either *mazara* Jordan and Snyder, 1901, or *marlina* Jordan and Evermann, 1926.

Although nominally on the border of the Atlantic Ocean, the Cape is, faunistically, almost completely isolated from the Atlantic by the wide belt of cold water that lies along the coast of South-West Africa. Because of the powerful westward warm Mozambique Current, the Cape is indeed connected far more closely with the tropical Indian Ocean than with any comparable even much closer area of the Atlantic. There is little doubt that *herschelii* travelled westwards with that current to and beyond Agulhas, where it was doubtless killed by the cold water. A comparable marlin was recently found floating dead in False Bay, Cape, and I have been sent a photograph, faded, but amply clear, of an approximately 10-ft. undoubted 'black' marlin found in Table Bay in 1923.

The original description and figure of *herschelii* accord quite satisfactorily with all marlins of comparable size found in southern Africa at and eastwards of the Cape, all of them 'black' marlins, apparently identical with those found in the Pacific and Indian Oceans. Among numerous specimens in South and East African waters, ranging from 45 to 450 lb. in weight, I have not yet found a single undoubted 'blue' marlin.

There is thus little doubt that if the 'black' marlin be accorded full specific distinction from the 'blue', it should bear the name *Makaira herschelii* (Gray), 1838.[1] This adds another to the long list of fishes first found at the Cape and later discovered over wide areas of the globe.

Death of Flamingoes in the Camargue

The sudden onset of cold weather in the Camargue during February of this year is reported to have killed off the wintering colony of flamingoes, *Phoenicopterus ruber roseus* Pall. There were said to be between 3,000 and 4,000 birds in the region. On a tour of the area during April 29–May 4, I saw at least 1,000 birds either in the air or settled around what appeared to be two nesting sites on the extreme eastern and western flanks of the Reserve. Mr. Luc Hoffmann, director of a private research station at Tour du Valat, is of the opinion that about 3,000 nests were occupied at the end of May. Nevertheless, he considers that probably 2,000 and possibly 3,000 birds perished earlier. He says he counted 200 dead birds in a very restricted area, and it may be significant that more than half of them were immature. Some birds tried to emigrate when the temperature began to fall; frozen corpses were found about 100 km. to the west of the Reserve; but a few partly frozen birds, recovered near his laboratory, were revived by warmth. Apparently no specific cause of the death of the birds can yet be given. One local observer said the legs of the flamingoes froze in contorted positions in mid-air. However, the present breeding stock is reported to be rather more than a good average.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, July 3

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. D. A. Denton (University of Melbourne): "Regulation of Sodium Ion Content in Sheep with Parotid Fistulae".*

Tuesday, July 3—Friday, July 6

Institute of Physics (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C 2)—Conference on "The Physics of Nuclear Reactors".

Wednesday, July 4

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. R. W. Riddell: "Mycology".* (Further lectures on July 18 and 25.)

Friday, July 6

British Psychological Society, Industrial Section (in Room 425, Birkbeck College, Malet Street, London, W.C.1), at 6 p.m.—Dr. C. Sofer: "Possible Contributions of Social Science to Industry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Guide Lecturer at the Geological Museum, London, S.W.7, for duties which include giving lectures and lecture-demonstrations to the general public—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting No S.4601/56/7 (July 4).

Shell B.P. Research Fellow in the Department of Aeronautical Engineering—The Secretary and Registrar, The University, Southampton (July 4).

Research Assistant (with research experience in biochemistry or the chemistry of natural products) in Chemical Microbiology in the Department of Botany—The Secretary, University College, Gower Street, London, W.C.1 (July 11).

Analytical Chemist (with a degree or higher national certificate in chemistry) mainly for plant material—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (July 14).

Assistant Lecturer or Lecturer in Electrical Engineering—The Registrar, University College, Singleton Park, Swansea (July 16).

Assistant Lecturer in the Department of Philosophy—The Registrar, The University, Manchester (July 21).

Research Demonstrator in Zoology—The Registrar, The University, Reading (July 21)

Assistant Lecturer in Geology—The Registrar (Room 9 O.R.B.), The University, Reading (July 23).

Lecturer in Zoology; Lecturer in Mathematics; and a Lecturer in Physics, at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (New Zealand, August 15).

Chair of Mathematics—The Registrar, University College of North Staffordshire, Keele, Staffs (August 31).

Senior Lecturer in Biochemistry at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Assistant Conservator of Forests, Class 1 (with a university degree in forestry and experience of teaching foresters) to administer the Forestry College at Prodromos, Cyprus, and to be responsible for the teaching of its syllabus—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD. 61/17/07.

Laboratory Technician (preferably with some photographic experience) in the Department of Physics to assist in radiation protection investigations—The House Governor, Royal Marsden Hospital, Fulham Road, London, S W.3.

Laboratory Technicians (with experience in research procedures including histology and laboratory animal dissection)—The Chief Technician, Clinico-Pathological Laboratories, Imperial Cancer Research Fund, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C 2.

Lecturer or Grade B Assistant in Inorganic Chemistry; and a Grade B Assistant in Organic Chemistry at the Wolverhampton and Staffordshire Technical College—The Clerk to the Joint Education Committee, Education Offices, North Street, Wolverhampton.

Lecturer (preferably with special interests in entomology, physiology or protozoology) in Zoology, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C 1.

Organic Chemist (with a degree in chemistry or biochemistry and postgraduate laboratory or research experience) to work at the Low Temperature Research Station, Cambridge, on the chromatographic analysis of potatoes in relation to blackening—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Research Assistant (graduate in physics, engineering or mathematics, the latter with laboratory experience) for experimental work on the flow of stratified fluids—The Meteorology Department, Imperial College, London, S.W.7.

Research Assistants (2) (with a suitable degree or equivalent qualification) in (a) Chemistry or Biology; or (b) Telecommunications or Physics—The Principal, Norwood Technical College, Knight's Hill, London, S.E.27.

Research Scholar in the Department of Textile Chemistry—The Registrar, College of Technology, Manchester 1.

Scientific Assistant (graduate, with proficiency in reading and abstracting foreign biological literature), and a Scientific Assistant (graduate in zoology, with experience in handling taxonomic problems and proficiency in reading foreign helminthological literature)—Prof. R. T. Leiper, Commonwealth Bureau of Helminthology, The White House, 103 St. Peter's Street, St. Albans, Herts.

Scientific Officer (with a first- or second-class honours degree in engineering or physics, and preferably with an interest in applied mechanics and thermodynamics) to work on wheel research and testing of crop driers—The Secretary, National Institute of Agricultural Engineering, Wrest Park, Silsoe, Beds.

Senior Plant Physiologist, Principal Scientific Officer grade (with a special knowledge and research experience of plant physiology) to develop a Physiology Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick.

Soil Survey Officer (with a good second-class honours degree in natural science, geography or agriculture) in the Department of Soil and Land Use Survey, Gold Coast, to supervise the field work of the survey, assist in the compilation of soil survey reports and maps, and assist in the training of junior staff—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.79/13/01.

CHEMICAL ENGINEERING PRACTICE

General Editor: HERBERT W. CREMER, C.B.E., M.Sc., F.R.I.C., M.I.Chem.E.
Past President of the Institution of Chemical Engineers, Past President of the Royal Institute of Chemistry

Managing Editor: TREFOR DAVIES, B.Sc., F.R.I.C., M.I.Chem.E.

This comprehensive work on Chemical Engineering as an integrated whole has been published to serve as a link between Physics, Chemistry and Engineering, to the better use of these sciences in process industries.

The professions represented by industrial executive and technical staffs are as varied as the processes employed in converting raw materials to the finished product. Information of value to all is scattered over a multitude of books and journals of differing professional interest. Recognition of these two facts pointed to the need for a wide-based work of an encyclopaedic nature, to act as a link between the professions and a common fund of information. CHEMICAL ENGINEERING PRACTICE **will meet this need.**

Volumes 1 & 2

LECTURES AND COURSES

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGY

POSTGRADUATE COURSE IN APPLIED GEOPHYSICS

The course is designed mainly as a basic training in methods of geophysical prospecting. It comprises lectures and practical and laboratory work with the main types of prospecting equipment, together with a summer field course of six weeks' duration. The normal entrance qualification is an honours degree in physics with some knowledge of geology, or an honours degree in geology with subsidiary physics, but graduates in other sciences who have reached a satisfactory standard in these subjects may be considered The course will commence in October, 1956, and finish the following September. Candidates will be required to submit a detailed report on their field work, and this will be combined with the results of a written examination for the award of a Master's degree The fee for the course, including the examination fee, is £71 1s. In certain instances a maintenance allowance may be awarded.

Further details may be obtained from the Registrar, the University, Edgbaston, Birmingham, 15, and applications for admission should be sent to him not later than September 1.

G. L. BARNES,
Secretary

The University,
Birmingham, 15.

UNIVERSITY OF BIRMINGHAM

FACULTY OF SCIENCE

The University is making special arrangements to provide training for boys and girls who will be qualified for admission to an Arts course to enable them to take an honours degree in either pure or applied science after four years of study The course will begin in October, 1956, and it is intended to help towards meeting the national need for more scientists and technologists.

Applications should be made as soon as possible to the Registrar, The University, Edgbaston, Birmingham 15, from whom further particulars can be obtained.

GEOFFREY TEMPLEMAN,
Registrar

OFFICIAL APPOINTMENTS

AUSTRALIAN NATIONAL UNIVERSITY

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

Applications are invited for the following posts in the Department of Medical Chemistry (Head of Department: Professor Adrien Albert): Two, Research Fellowships (Organic Chemists); one Senior Research Fellowship; and one Research Fellowship (or two Research Fellowships). (Physical Chemists, with experience in spectroscopy and electrochemistry). The main work of the Department is on heterocyclic compounds, especially pteridines, pyrimidines and purines and on chelation of metals. Successful candidates will be expected to take up duties in Canberra in September, or soon thereafter, when the Department will be transferred from London to newly completed and well equipped laboratories. Commencing salaries will be determined within the ranges £A.1,900 to £A.2,350 (Senior Research Fellowship) and £A.1,200 to £A.1,800 (Research Fellowship) Appointments will be for three years in the first instance, from date of embarkation. Reasonable travel expenses will be paid and assistance will be given on housing. Superannuation is on the F.S.S.U. pattern.

Further particulars should be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close on July 23, 1956.

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

A vacancy exists for a Biochemist to study the chemical properties of cervical mucus in relation to the action of sex hormones, initially for a, period of one year, with probable extension Commencing salary up to £1,100 according to qualifications and experience. Candidates should possess first- or second-class honours degree in biochemistry, or equivalent qualification, with postgraduate research experience

Applications, with names of two referees, to the Secretary, N I R D., Shinfield, Reading Quote reference 56/3.

ATOMIC ENERGY RESEARCH ESTABLISHMENT

HARWELL

requires an ASSISTANT EXPERIMENTAL
OFFICER (male) in the
MEDICAL DIVISION
(Analytical Section)

The work, involving the analysis of radioactive and other toxic agents in biological specimens and in air, though of a routine nature is varied, and opportunity to improve on existing methods and to develop new ones will be given.

Applicants should possess G C.E. advanced level in science subjects, including mathematics and chemistry, or equivalent qualifications. The successful candidate will be expected to become a student of the Royal Institute of Chemistry. Deferment can usually be obtained to allow the student to sit for the Institute's examination, although applicants should preferably have completed their National Service.

Salary: £353 (at age 18) to £756 per annum

Contributory pension scheme; five-day week, excellent working conditions and good leave allowances.

Married officers living outside the Establishment's transport area will be eligible for housing under Authority's arrangements or, alternatively, substantial assistance towards legal expenses incurred in house purchase will be available.

Send postcard for application form, which must be returned by July 10, 1956, to Establishment Officer, A.E.R.E, Harwell, Didcot, Berks, quoting reference 541/34.

UNIVERSITY COLLEGE OF SWANSEA

Applications are invited for either an Assistant Lectureship or a Lectureship in Electrical Engineering. It is desirable but not essential that candidates' interest be in one of the fields: transistor circuitry; control systems, which can be large power speed control apparatus; or aerials. Salaries: Assistant Lectureship, not less than £550 per annum, Lectureship £650 by £50 to £1,350 per annum. Commencing salary in each case will be at a point on the appropriate scale according to age, qualifications, and experience. Membership of the F.S.S.U. and children's allowance scheme.

Further particulars may be obtained from the Registrar, University College, Singleton Park, Swansea, to whom applications (six copies) must be sent by July 16, 1956.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer in Engineering (Mechanical). Preference will be given to candidates with a major interest in heat transfer. A knowledge of some aspect of nuclear engineering would be an advantage. University regulations permit teaching staff to read for the degrees of M Sc. and Ph.D. Applications will also be considered from engineers who would be interested in a temporary appointment for two or more years. Salary scale: £650 to £1,350 per annum. Membership of F.S S U. and children's allowance scheme. Initial salary according to qualifications and experience.

Applications should be sent not later than July 9, 1956, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained Applications by airmail (no forms), will be considered from overseas candidates.

COMMONWEALTH BUREAU OF HELMINTHOLOGY

Applications for the post of Scientific Assistant are invited from men or women graduates with proficiency in reading and abstracting foreign biological literature. Salary £445 to £1,170, with pay supplement £69 to £160 Starting salary according to age, qualifications and experience. Increments up to two years granted for completed years of compulsory National Service and two further increments after two years' satisfactory service Provision for superannuation.

Applications, with references, should be addressed to Professor R. T. Leiper, Commonwealth Bureau of Helminthology, The White House, 103 St. Peter's Street, St Albans, Herts.

ROYAL TECHNICAL COLLEG

SALFORD

Acting Principal: J. F. Yates, B Sc, M Sc
M.I.E E

The Governors invite applications from pe
with a degree and/or professional equivalent
the undermentioned posts:

Chemistry Department. Senior Lecturer in
organic Chemistry, to plan and supervise
teaching of inorganic chemistry up to hon
degree standard Assistant Lecturer, Grade B
teach general chemistry.

Physics Department. Assistant Lecturer, Gr
B, who should offer one branch of applied phys
and pure physics to the standard of G.C.E.
vanced level. There will be opportunities
more advanced work.

Salaries, which are offered in accordance
the Burnham Technical Report, 1954, are subj
to revision under the new Burnham Scales wh
it is hoped, will be published shortly. Se
Lecturer: £1,065 to £1,215 (men); £852 to £9
plus two-sevenths differential (women).

For further particulars and forms of app
tion please send a stamped addressed envelop
The Acting Principal, Royal Technical Colle
Salford, 5. Applications should be returned
soon as possible.

R. RIBBLESDALE THORNTON
Clerk to the Governo

VICTORIA UNIVERSITY COLLEG

WELLINGTON, NEW ZEALAND

The Council of Victoria University Colle
proposes shortly to appoint a Lecturer in t
Department of Botany, and invites applicati
from suitably qualified persons for this post. T
salary will be £985 p.a, rising by annual inc
ments of £50 to £1,235. The initial salary w
be determined according to the qualifications a
experience of the appointee. An allowance
made towards travelling expenses, and the su
cessful applicant would be expected to take
his duties on February 1, 1957, or at such ea
or later date as may be agreed on by the Colle
Council.

Further particulars and information as to
method of application may be obtained from
Secretary, Association of Universities of t
British Commonwealth, 36 Gordon Square, Lo
don, W C 1. The closing date for the rece
of applications, in New Zealand and London,
August 15, 1956.

VICTORIA UNIVERSITY COLLEG

WELLINGTON, NEW ZEALAND

The Council of Victoria University Coll
proposes shortly to initiate the teaching of
chemistry through the appointment of a Sen
Lecturer in Biochemistry in the Department
Chemistry, and invites applications from suita
qualified persons for this post The salary
be £1,275 per annum, rising by annual in
ments of £50 to £1,575 per annum The init
salary will be determined according to t
qualifications and experience of the appoint
An allowance is made towards travelling e
penses and the successful applicant would
expected to take up his duties on February
1957, or at such other date as may be agre
upon

Further particulars and information as to
method of application may be obtained fr
the Secretary, Association of Universities of
British Commonwealth, 36 Gordon Squa
London, W C.1. The closing date for the
ceipt of applications, in New Zealand a
London, is August 31, 1956.
